The Moxa W311/321/341 are RISC-based ready-to-run wireless embedded computers with 802.11a/b/g WLAN, one 10/100 Mbps Ethernet port, an internal SD socket, 1/2/4 RS-232/422/485 serial ports, two USB 2.0 hosts, one relay output channel, and pre-installed Linux operating system. The W311/321/341 offer high performance communication and unlimited storage in a super compact, palm-size ARM9 box. The W300 Series is the right solution for embedded applications that are used in hard-to-wire environments and that require a large amount of memory, but that must be housed in a small space without sacrificing performance.

The following topics are covered in this chapter:

- ❑ **Overview**
- ❑ **Software Architecture**
 - Journaling Flash File System (JFFS2)
 - Software Package

Overview

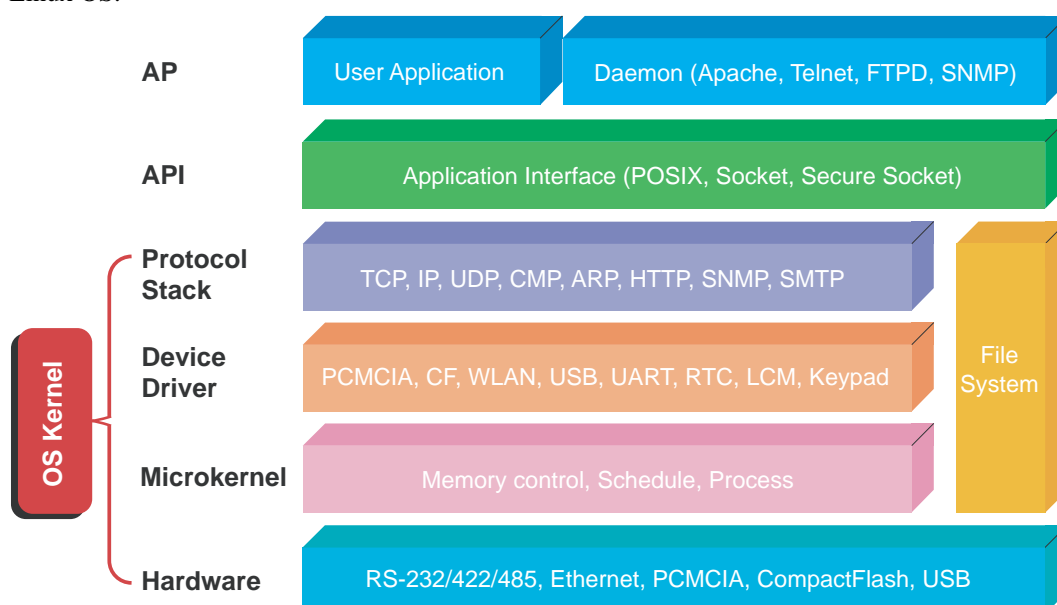

The W311/321/341 wireless embedded computers support 802.11a/b/g wireless LANs with data encryption functions, including the common WEP and powerful WPA and WPA2, to establish a secure transmission tunnel over a WLAN.

W300 Series Embedded Computers use a Moxa ART 192 Mhz RISC CPU. Unlike the X86 CPU, which uses a CISC design, the RISC architecture and modern semiconductor technology provide these embedded computers with a powerful computing engine and communication functions, but without generating a lot of heat. A 16 MB NOR Flash ROM and on-board SDRAM (64 MB for W341 and 32 MB for W311/321) give you enough memory to install your application software directly on the embedded computer. In addition, dual LAN ports are built right into the RISC CPU. This network capability, in combination with the ability to control serial devices, makes the W300 Series ideal as communication platforms for data acquisition and industrial control applications.

The pre-installed Linux operating system (OS) provides an open software operating system for your software program development. Software written for desktop PCs can be easily ported to the computer with a GNU cross compiler, without needing to modify the source code. The OS, device drivers (e.g., serial and buzzer control), and your own applications, can all be stored in the NOR Flash memory.

Software Architecture

The Linux operating system that is pre-installed in the W311/321/341 follows the standard Linux architecture, making it easy to accept programs that follow the POSIX standard. Program porting is done with the GNU Tool Chain provided by Moxa. In addition to Standard POSIX APIs, device drivers for the USB storage, buzzer and Network controls, and UART are also included in the Linux OS.

The W311/321/341's built-in Flash ROM is partitioned into **Boot Loader, Linux Kernel, Root File System**, and **User directory** partitions.

In order to prevent user applications from crashing the Root File System, the W311/321/341 use a specially designed **Root File System with Protected Configuration** for emergency use. This **Root File System** comes with serial and Ethernet communication capability for users to load the **Factory Default Image** file. The user directory saves the user's settings and application. To improve system reliability, the W311/321/341 have a built-in mechanism that prevents the system from crashing. When the Linux kernel boots up, the kernel will mount the root file system for read only, and then enable services and daemons. At the same time, the kernel will start searching for system configuration parameters via *rc* or *inittab*.

Normally, the kernel uses the Root File System to boot up the system. The Root File System is protected, and cannot be changed by the user. This type of setup creates a "safe" zone.

For more information about the memory map and programming, refer to Chapter 6, *Programmer's Guide*.

Journaling Flash File System (JFFS2)

The Root File System and User directory in the flash memory is formatted with the **Journaling Flash File System (JFFS2)**. The formatting process places a compressed file system in the flash memory. This operation is transparent to the user.

The Journaling Flash File System (JFFS2), which was developed by Axis Communications in Sweden, puts a file system directly on the flash, instead of emulating a block device. It is designed for use on flash-ROM chips and recognizes the special write requirements of a flash-ROM chip. JFFS2 implements wear-leveling to extend the life of the flash disk, and stores the flash directory structure in the RAM. A log-structured file system is maintained at all times. The system is always consistent, even if it encounters crashes or improper power-downs, and does not require *fsck* (file system check) on boot-up.

JFFS2 is the newest version of JFFS. It provides improved wear-leveling and garbage-collection performance, improved RAM footprint and response to system-memory pressure, improved concurrency and support for suspending flash erases, marking of bad sectors with continued use of the remaining good sectors (enhancing the write-life of the devices), native data compression inside the file system design, and support for hard links.

The key features of JFFS2 are:

- Targets the Flash ROM Directly
- Robustness
- Consistency across power failures
- No integrity scan (fsck) is required at boot time after normal or abnormal shutdown
- Explicit wear leveling
- Transparent compression

Although JFFS2 is a journaling file system, this does not preclude the loss of data. The file system will remain in a consistent state across power failures and will always be mountable. However, if the board is powered down during a write then the incomplete write will be rolled back on the next boot, but writes that have already been completed will not be affected.

Additional information about JFFS2 is available at:

<http://sources.redhat.com/jffs2/jffs2.pdf>

<http://developer.axis.com/software/jffs/>

<http://www.linux-mtd.infradead.org/>

Software Package

Boot Loader	Moxa Boot Loader (v1.2)
Kernel	Linux 2.6.9
Protocol Stack	ARP, PPP, CHAP, PAP, IPv4, ICMP, TCP, UDP, DHCP, FTP, SNMP V1/V3, HTTP, NTP, NFS, SMTP, SSH 1.0/2.0, SSL, Telnet, PPPoE, OpenVPN
File System	JFFS2, NFS, Ext2, Ext3, VFAT/FAT
OS shell command	Bash
Busybox	Linux normal command utility collection
Utilities	
tinylogin	login and user manager utility
telnet	telnet client program
ftp	FTP client program
smtpclient	email utility
scp	Secure file transfer Client Program
Daemons	
pppd	dial in/out over serial port daemon
snmpd	snmpd agent daemon
telnetd	telnet server daemon
inetd	TCP server manager program
ftpd	ftp server daemon
apache	web server daemon
sshd	secure shell server
openvpn	virtual private network
openssl	open SSL
Linux Tool Chain	
Gcc (V3.3.2)	C/C++ PC Cross Compiler
GDB (V5.3)	Source Level Debug Server
Glibc (V2.2.5)	POSIX standard C library

In this chapter, we explain how to connect the W311/321/341, how to turn on the power, how to get started programming, and how to use the W311/321/341's other functions.

The following topics are covered in this chapter:

- ❑ **Powering on the W311/321/341**
- ❑ **Connecting the W311/321/341 to a PC**
 - Serial Console
 - Telnet Console
 - SSH Console
- ❑ **Configuring the Ethernet Interface**
 - Modifying Network Settings with the Serial Console
 - Modifying Network Settings over the Network
- ❑ **Configuring the WLAN**
 - IEEE802.11a/b/g
- ❑ **Using WPA_SUPPLICANT to Support WPA and WPA2**
- ❑ **SD Slot and USB for Storage Expansion**
- ❑ **Test Program—Developing Hello.c**
 - Installing the Tool Chain (Linux)
 - Checking the Flash Memory Space
 - Compiling Hello.c
 - Uploading and Running the “Hello” Program
- ❑ **Developing Your First Application**
 - Testing Environment
 - Compiling tcps2.c
 - Uploading and Running the “tcps2-release” Program
 - Testing Procedure Summary

Powering on the W311/321/341

Connect the SG wire to the shielded contact located in the upper left corner of the W311/321/341, and then power on the computer by connecting it to the power adaptor. It takes about 30 to 60 seconds for the system to boot up. Once the system is ready, the Ready LED will light up.

NOTE After connecting the W311/321/341 to the power supply, it will take about 30 to 60 seconds for the operating system to boot up. The green Ready LED will not turn on until the operating system is ready.

ATTENTION

This product is intended to be supplied by a Listed Power Unit with output marked “LPS” and rated for 12-48 VDC, 600 mA (minimum requirements).

Connecting the W311/321/341 to a PC

There are two ways to connect the W311/321/341 to a PC: through the serial console and by Telnet over the network.

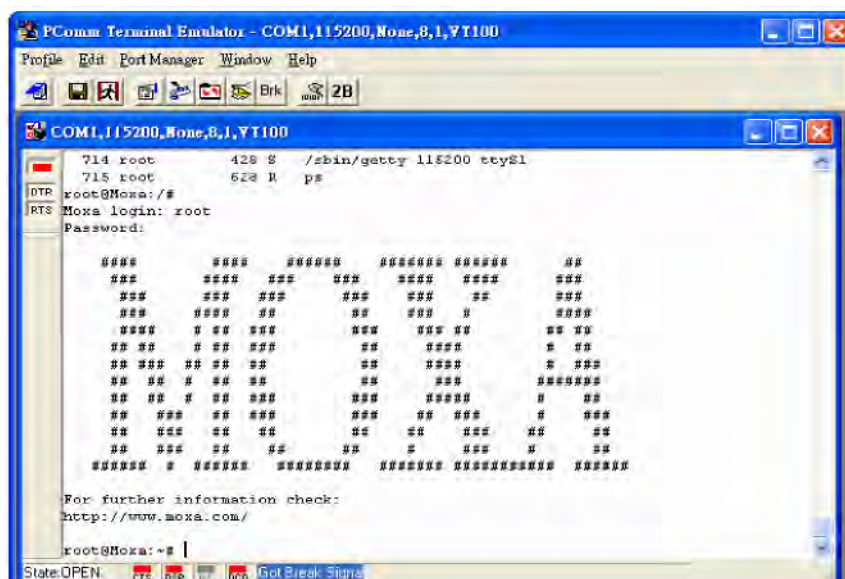

Serial Console

The serial console gives users a convenient way of connecting to the W311/321/341. This method is particularly useful when using the computer for the first time. The serial console is useful for connecting the W311/321/341 when you do not know either of the two IP addresses.

Use the serial console port settings shown below.

Baudrate	115200 bps
Parity	None
Data bits	8
Stop bits:	1
Flow Control	None
Terminal	VT100

The following window will open when a connection has been established.

To log in, type the Login name and password as requested. The default values are both **root**:

```
Login:    root
Password: root
```

Telnet Console

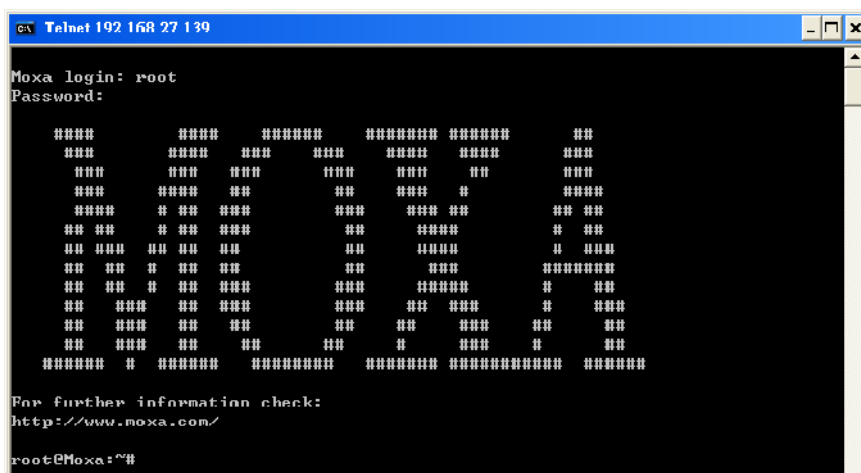

If you know at least one of the two IP addresses and netmasks, then you can use Telnet to connect to the W311/321/341's console utility. The default IP address and Netmask for each of the two ports are given below:

	Default IP Address	Netmask
LAN 1	192.168.3.127	255.255.255.0
WIRELESS LAN	192.168.4.127	255.255.255.0

Use a cross-over Ethernet cable to connect directly from your PC to the W311/321/341. You should first modify your PC's IP address and netmask so that your PC is on the same subnet as one of W311/321/341's two LAN ports. For example, if you connect to LAN 1, you can set your PC's IP address to 192.168.3.126 and netmask to 255.255.255.0. If you connect to the WIRELESS LAN, you can set your PC's IP address to 192.168.4.126 and netmask to 255.255.255.0 using a wireless AP router.

Use a straight-through Ethernet cable to connect to a hub or switch that is connected to your local LAN. The default IP addresses and netmasks are shown above. To log in, type the Login name and password as requested. The default values are both **root**:

```
Login:    root
Password: root
```

You can proceed with configuring the network settings of the target computer when you reach the bash command shell. Configuration instructions are given in the next section.

ATTENTION

Serial Console Reminder

Remember to choose VT100 as the terminal type. Use the cable CBL-4PINDB9F-100, which comes with the W311/321/341, to connect to the serial console port.

Telnet Reminder

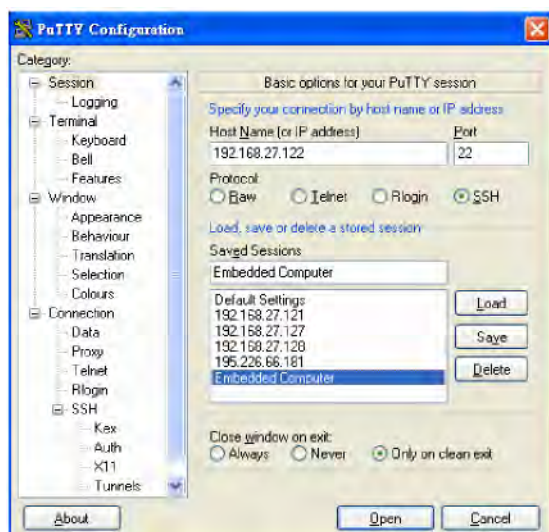

When connecting to the W311/321/341 over a LAN, you must configure your PC's Ethernet IP address to be on the same subnet as the W341 that you wish to contact. If you do not get connected on the first try, re-check the serial and IP settings, and then unplug and re-plug the power cord.

SSH Console

The W311/321/341 support an SSH Console to provide users with better security options.

Windows Users

Click on the link <http://www.chiark.greenend.org.uk/~sgtatham/putty/download.html> to download PuTTY (free software) to set up an SSH console for the W311/321/341 in a Windows environment. The following figure shows a simple example of the configuration that is required.

Linux Users

From a Linux machine, use the “ssh” command to access the W311/321/341’s console utility via SSH.

```
#ssh 192.168.3.127
```

Select **yes** to complete the connection.

```
[root@bee_notebook root]# ssh 192.168.3.127
The authenticity of host '192.168.3.127 (192.168.3.127)' can't be established.
RSA key fingerprint is 8b:ee:ff:84:41:25:fc:cd:2a:f2:92:8f:cb:1f:6b:2f.
Are you sure you want to continue connection (yes/no)? yes_
```

NOTE SSH provides better security compared to Telnet for accessing the W311/321/341’s console utility over the network.

Configuring the Ethernet Interface

The network settings of the W311/321/341 can be modified with the serial console port, or online over the network.

Modifying Network Settings with the Serial Console

In this section, we use the serial console to configure the network settings of the target computer.

1. Follow the instructions given in a previous section to access the Console Utility of the target computer via the serial console port, and then type `#cd /etc/network` to change directories.

2. Type `#vi interfaces` to edit the network configuration file with vi editor. You can configure the Ethernet ports of the W341 for **static** or **dynamic** (DHCP) IP addresses.

Static IP addresses

As shown in the table below, 4 network addresses must be modified: **address**, **network**, **netmask**, and **broadcast**. The default IP address for LAN1 is 192.168.3.127, with default netmask of 255.255.255.0.

Dynamic IP addresses

By default, the W311/321/341 are configured for “static” IP addresses. To configure one or both LAN ports to request an IP address dynamically, replace **static** with **dhcp** and then delete the address, network, netmask, and broadcast lines.

Default Setting for LAN1	Dynamic Setting using DHCP
<pre>iface eth0 inet static address 192.168.3.127 network: 192.168.3.0 netmask 255.255.255.0 broadcast 192.168.3.255</pre>	<pre>iface eth0 inet dhcp</pre>

3. After the boot settings of the LAN interface have been modified, issue the following command to activate the LAN settings immediately:

```
#/etc/init.d/networking restart
```

NOTE After changing the IP settings, use the networking restart command to activate the new IP address.

Modifying Network Settings over the Network

IP settings can be activated over the network, but the new settings will not be saved to the flash ROM without modifying the file `/etc/network/interfaces`.

For example, type the command `#ifconfig eth0 192.168.1.1` to change the IP address of LAN1 to 192.168.1.1.

```
root@Moxa:~# ifconfig eth0 192.168.27.125
root@Moxa:~# _
```

Configuring the WLAN

IEEE802.11a/b/g

Use one of the following options to configure the WLAN for IEEE802.11a/b/g:

1. Using the config file to set up your wireless system

The config file is **/etc/wireless.conf**. The config file is read by the OS when the W311/321/341 unit boots up. You may also use the **load_wlan** command to force your wireless to run the config file and set up your wireless LAN card after the W311/321/341 unit is already up and running. The **/etc/wireless.conf** file format is shown below:

[illegible]

/etc/wireless.conf Format:

```
DEVICE=eth1
MODE=managed ESSID=any
KEY=any
```

/etc/wireless.conf Item list:

DEVICE → indicates your wireless interface

MODE → indicates your wireless mode, such as ad-hoc, managed, master

ESSID → indicates your wireless ESSID NAME

KEY → indicates your wireless WEP key

CHANNEL → indicates your wireless channel setting

MACMODE → indicates your wireless macmode setting, such as 1 (mixed mode), 2 (pure g_mode), 3 (pure b_mode), 4 (pure a_mode)

REGION → indicates your wireless country region setting

WIRELESS_SUPPLICANT → If set to Y, load_wlan will call /etc/init.d/wpa.sh and open wireless WPA and WPA2

MOXA_REPEAT → If set to Y, load_wlan will call ipriv eth1 set_moxa_repeat to establish ad-hoc mode using repeat function

If you want to use WPA and WPA2, please refer to the subsection “Using WPA_SUPPLICANT to Support WPA and WPA2” on page 2-11.

2. Use the command `#vi /etc/networking/interfaces` to open the “interfaces” configuration file with vi editor, and then edit the 802.11g network settings

Static IP addresses:

As shown in the table below, 4 network addresses need to be modified: **address**, **network**, **netmask**, and **broadcast**. The default WIRELESS LAN IP address is 192.168.4.127.

Dynamic IP addresses:

By default, the W311/321/341 are configured for “static” IP addresses. To configure one or both LAN ports to request an IP address dynamically, replace **static** with **dhcp** and then delete the address, network, netmask, and broadcast lines.

Default Setting for WIRELESS LAN	Dynamic Setting using DHCP
<pre>iface eth1 inet static address 192.168.4.127 network: 192.168.4.0 netmask 255.255.255.0 broadcast 192.168.4.255</pre>	<pre>iface eth1 inet dhcp</pre>

After the boot settings of the LAN interface have been modified, issue the following command to activate the LAN settings immediately:

```
#/etc/init.d/networking restart
```

3. Using `iwconfig` / `iwpriv` Utility to set up the wireless configuration

Using `iwpriv eth1 essid ESSIDNAME`

`iwconfig eth1 essid ESSIDNAME` → set up wireless essid

`iwconfig eth1 key KEYVALUE open` → set up wireless wep key

`iwconfig eth1 mode infra` → set up wireless mode

CountryRegion—Sets the channels for your particular country / region

Using `iwpriv eth1 set_Region REGION`

REGION	Explanation
1 (USA) (default)	Use 802.11g channels 1 to 11
2 (Taiwan/Europe)	Use 802.11g channels 1 to 13
3 (France)	Use 802.11g channels 10 to 13
4 (Japan)	Use 802.11g channels 1 to 14
5 (Israel)	Use 802.11g channels 3 to 9
6 (Mexico)	Use 802.11g channels 10 , 11

WirelessMode—Sets the wireless mode

Using `iwpriv eth1 set_mac_mode Setting`

Note: `infrastructure` just support mixed/a mode; `Ad-hoc` support b/g/a mode

Setting	Explanation
1 (default)	11a/mixed(b,g)
2	11g only
3	11b only
4	11a only

SSID—Sets the softAP SSID

Using iwconfig eth1 essid **Setting**

Setting
Any 32-byte string

NetworkType—Sets the wireless operation mode

Using iwconfig eth1 mode **Setting**

Setting	Explanation
managed	Infrastructure mode (uses access points to transmit data)
ad-hoc	Adhoc mode (transmits data from host to host)

Channel—Sets the channel

Using iwconfig eth1 channel **Setting**

Note: Infrastruct couldn't set channel

Freq—Sets the channel frequency

Using iwconfig eth1 freq **Setting(G,M,K)**

Note: Infrastruct couldn't set freq

802.11b,g Channel and Frequency Table

Channel	Frequency
1	2412 (K)
2	2417 (K)
3	2422 (K)
4	2427 (K)
5	2432 (K)
6	2437 (K)
7	2442 (K)
8	2447 (K)
9	2452 (K)
10	2457 (K)
11	2462 (K)
12	2467 (K)
13	2472 (K)
14	2484 (K)

802.11a Channel and Frequency Table

Channel	Frequency
36	5180 (K)
40	5200 (K)
44	5220 (K)
48	5240 (K)
52	5260 (K)
56	5280 (K)

60	5300 (K)
64	5320 (K)
100	5500 (K)
104	5520 (K)
108	5540 (K)
112	5560 (K)
116	5580 (K)
120	5600 (K)
124	5620 (K)
128	5640 (K)
132	5660 (K)
136	5680 (K)
140	5700 (K)
184	4920 (K)
188	4940 (K)
192	4960 (K)
196	4980 (K)
8	5040 (K)
12	5060 (K)
16	5080 (K)
34	5170 (K)
38	5190 (K)
42	5210 (K)
46	5230 (K)
149	5745 (K)
153	5765 (K)
157	5785 (K)
161	5805 (K)
165	5825 (K)

AuthMode—Sets the authentication mode

Using iwpriv eth1 set_auth **Setting**

Setting	Explanation
0	OPEN
1	SHARED
2	AUTO (default)

KeyStr—Sets Key Support string key and hex key

Encryp Type—Just Support **NONE**, **WEP64** and **WEP128** depend on your key length

Using iwpriv eth1 key s:KEYVALUE (open) → support string key

Using iwpriv eth1 key KEYVALUE (open) → support hex key

RTSThreshold—Sets the RTS threshold

Using iwpriv eth1 rts Setting

Setting
1 to 2347

FragThreshold—Sets the fragment threshold

Using iwpriv eth1 frag Setting

Setting
256 to 2346

Moxa Repeat—Sets the Repeat function through adhoc method

Using iwpriv eth1 set_moxa_repeat

Using WPA_SUPPLICANT to Support WPA and WPA2

This embedded computer supports the WPA and WPA2 functions using the /bin/wpa_supplicant program. We wrote a shell script to help you use this function:

Step 1:

Edit the **ssid** and **psk** variables in the file **etc/wpa_supplicant.conf**.

```
network={
    ssid="12345678901"
    key_mgmt=WPA-PSK
    proto=WPA RSN
    pairwise=TKIP CCMP
    group=TKIP CCMP
    psk="0987654321234"
}
```

Step 2:

Type **/etc/init.d/wpa.sh eth1 start** to enable this function. To stop the function, type **/etc/init.d/wpa.sh eth1 stop**

SD Slot and USB for Storage Expansion

The W311/321/341 provide an SD slot for storage expansion. Moxa provides an SD flash disk for plug & play expansion that allows users to plug in a Secure Digital (SD) memory card compliant with the SD standard V1.0 for up to 1 GB of additional memory space. The following steps show you how to install SD card into the W311/321/341.

W311/321

The SD slot is located on the right side of the W311/321 enclosure. To install an SD card, you must first remove the SD slot's protective cover to access the slot, and then plug the SD card directly into the slot.

The SD card will be mounted at `/mnt/sd`. Detailed installation instructions are shown below:

Step 1: Use a screwdriver to remove the screws holding the SD slot's outer cover.

Step 2: After removing the cover, insert the SD memory card as shown.

W341

The SD slot is located on the front panel of the W341. To install an SD card, you must first remove the SD slot's protective cover to access the slot, and then plug the SD card directly into the slot.

The SD card will be mounted at `/mnt/sd`. Detailed installation instructions are shown below:

Step 1: Use a screwdriver to remove the screws holding the SD slot's outer cover, and then remove the cover.

Step 2: Insert the SD memory card as shown.

NOTE: To remove the SD card from the slot, press the SD card in slightly with your finger, and then remove your finger to cause the card to spring out partially. You may now grasp the top of the card with two fingers and pull it out.

Before removing the SD card, remember to type `/sync` to ensure that your data has been written.

In addition to the SD socket, two USB 2.0 ports are located on the W341's upper panel. The USB host is also designed for storage expansion. To use a USB flash disk to expand the storage space, plug the USB flash disk into the USB port. The flash disk will be detected automatically, and its file partition will be mounted into the OS. The USB storage will be mounted in one of four directories: `/mnt/usbstorage1`, `/mnt/usbstorage2`, `/mnt/usbstorage3`, or `/mnt/usbstorage4`.

Test Program—Developing Hello.c

In this section, we use the standard “Hello” programming example to illustrate how to develop a program for the W311/321/341. In general, program development involves the following seven steps.

Step 1:

Connect the W311/321/341 to a Linux PC.

Step 2:

Install Tool Chain (GNU Cross Compiler & glibc).

Step 3:

Set the cross compiler and glibc environment variables.

Step 4:

Code and compile the program.

Step 5:

Download the program to the W311/321/341 using FTP or NFS.

Step 6:

Debug the program

→ If bugs are found, return to Step 4.

→ If no bugs are found, continue with Step 7.

Step 7:

Back up the user directory (distribute the program to additional W311/321/341 units if needed).

Installing the Tool Chain (Linux)

The Linux Operating System must be pre-installed in the PC before installing the W311/321/341 GNU Tool Chain. Fedora core or compatible versions are recommended. The Tool Chain requires approximately 100 MB of hard disk space on your PC. The W311/321/341 Tool Chain software is located on the W311/321/341 CD. To install the Tool Chain, insert the CD into your PC and then issue the following commands:

```
#mount /dev/cdrom /mnt/cdrom
#sh /mnt/cdrom/tool-chain/linux/install.sh
```

The Tool Chain will be installed automatically on your Linux PC within a few minutes. Before compiling the program, be sure to set the following path first, since the Tool Chain files, including the compiler, link, library, and include files are located in this directory.

```
PATH=/usr/local/arm-linux/bin:$PATH
```

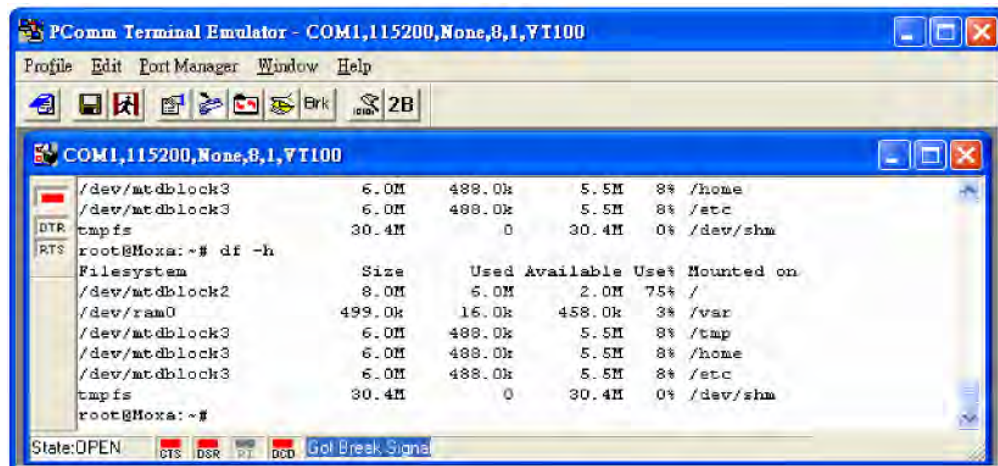

Setting the path allows you to run the compiler from any directory.

NOTE	Refer to Appendix B for an introduction to the Windows Tool Chain. In this chapter, we use the Linux tool chain to illustrate the cross compiling process.
-------------	--

Checking the Flash Memory Space

If the flash memory is full, you will not be able to save data to the Flash ROM. Use the following command to calculate the amount of “Available” flash memory:

```
/>df -h
```

```
COM1,115200,None,8,1,V T100
Profile Edit Port Manager Window Help
COM1,115200,None,8,1,V T100
/dev/mtdblock3 6.0M 488.0k 5.5M 8% /home
/dev/mtdblock3 6.0M 488.0k 5.5M 8% /etc
tmpfs 30.4M 0 30.4M 0% /dev/shm
root@Moxa:~# df -h
Filesystem      Size      Used Available Use% Mounted on
/dev/mtdblock2  8.0M       6.0M      2.0M  75% /
/dev/ram0      499.0k     16.0k    488.0k   3% /var
/dev/mtdblock3  6.0M     488.0k    5.5M   8% /tmp
/dev/mtdblock3  6.0M     488.0k    5.5M   8% /home
/dev/mtdblock3  6.0M     488.0k    5.5M   8% /etc
tmpfs          30.4M       0     30.4M   0% /dev/shm
root@Moxa:~#
```

If there isn't enough “Available” space for your application, you will need to delete some existing files. To do this, connect your PC to the W311/321/341 with the console cable, and then use the console utility to delete the files from the W311/321/341's flash memory. To check the amount of free space available, look at the directories in the read/write directory `/dev/mtdblock3`. Note that the directories `/home` and `/etc` are both mounted on the directory `/dev/mtdblock3`.

NOTE If the flash memory is full, you will need to free up some memory space before saving files to the Flash ROM.

Compiling Hello.c

The package CD contains several example programs. Here we use **Hello.c** as an example to show you how to compile and run your applications. Type the following commands from your PC to copy the files used for this example from the CD to your computer's hard drive:

```
# cd /tmp/
# mkdir example
# cp -r /mnt/cdrom/example/* /tmp/example
```

To compile the program, go to the **Hello** subdirectory and issue the following commands:

```
#cd example/hello #make
```

You should receive the following response:

```
[root@localhost hello]# make
/usr/local/arm-linux/bin/arm-linux-gcc -o hello-release hello.c
/usr/local/arm-linux/bin/arm-linux-strip -s hello-release
/usr/local/arm-linux/bin/arm-linux-gcc -ggdb -o hello-debug hello.c
[root@localhost hello]# _
```

Next, execute **make** to generate **hello-release** and **hello-debug**, which are described below:

hello-release—an ARM platform execution file (created specifically to run on the W311/321/341)

hello-debug—an ARM platform GDB debug server execution file (see Chapter 5 for details about the GDB debug tool).

NOTE Since Moxa's tool chain places a specially designed **Makefile** in the directory **/tmp/example/hello**, be sure to type the **#make** command from within that directory. This special Makefile uses the mxscale-gcc compiler to compile the hello.c source code for the Xscale environment. If you type the **#make** command from within any other directory, Linux will use the x86 compiler (for example, cc or gcc).

Refer to Chapter 5 to see a Makefile example.

Uploading and Running the "Hello" Program

Use the following commands to upload **hello-release** to the W311/321/341 by FTP.

1. From the PC, type:

```
#ftp 192.168.3.127
```
2. Use the bin command to set the transfer mode to Binary mode, and then use the put command to initiate the file transfer:

```
ftp> bin
ftp> cd /home
ftp> put hello-release
```
3. From the W311/321/341, type:

```
# chmod +x hello-release
# ./hello-release
```

The word **Hello** will be printed on the screen.

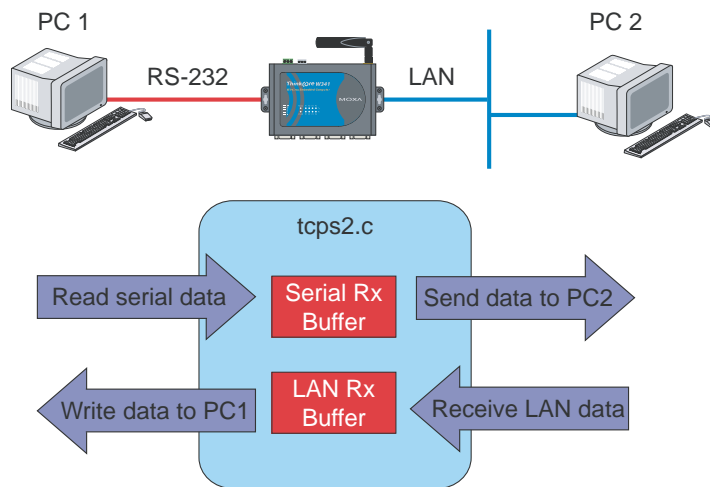

```
root@Moxa:~# ./hello-release
Hello
```

Developing Your First Application

We use the tcps2 example to illustrate how to build an application. The procedure outlined in the following subsections will show you how to build a TCP server program plus serial port communication that runs on the W311/321/341.

Testing Environment

The tcps2 example demonstrates a simple application program that delivers transparent, bi-directional data transmission between the W311/321/341's serial and Ethernet ports. As illustrated in the following figure, the purpose of this application is to transfer data between PC 1 and the W311/321/341 through an RS-232 connection. At the remote site, data can be transferred between the W311/321/341's Ethernet port and PC 2 over an Ethernet connection.

Compiling tcps2.c

The source code for the tcps2 example is located on the CD-ROM at **CD-ROM://example/TCPServer2/tcps2.c**. Use the following commands to copy the file to a specific directory on your PC. We use the directory **/home/w341/1st_application/**. Note that you need to copy 3 files—Makefile, tcps2.c, tcpsp.c—from the CD-ROM to the target directory.

```
#mount -t iso9660 /dev/cdrom /mnt/cdrom
#cp /mnt/cdrom/example/TCPServer2/tcps2.c/home/w341/1st_application/tcps2.c
#cp /mnt/cdrom/example/TCPServer2/tcpsp.c/home/w341/1st_application/tcpsp.c
#cp /mnt/cdrom/example/TCPServer2/Makefile.c/home/w341/1st_application/Makefile
```

Type **#make** to compile the example code:

You will get the following response, indicating that the example program was compiled successfully.

```
root@server11:/home/w341/1st_application

[root@server11 1st_application]# pwd
/home/w341/1st_application
[root@server11 1st_application]# ll
total 20
-rw-r--r-- 1 root root 514 Nov 27 11:52 Makefile
-rw-r--r-- 1 root root 4554 Nov 27 11:52 tcps2.c
-rw-r--r-- 1 root root 6164 Nov 27 11:55 tcps2.c
[root@server11 1st_application]# make_
/usr/local/arm-linux/bin/arm-linux-gcc -o tcps2-release tcps2.c
/usr/local/arm-linux/bin/arm-linux-strip -s tcps2-release
/usr/local/arm-linux/bin/arm-linux-gcc -o tcpsp-release tcpsp.c
/usr/local/arm-linux/bin/arm-linux-strip -s tcpsp-release
/usr/local/arm-linux/bin/arm-linux-gcc -ggdb -o tcps2-debug tcps2.c
/usr/local/arm-linux/bin/arm-linux-gcc -ggdb -o tcpsp-debug tcpsp.c
[root@server11 1st_application]# ll
total 92
-rw-r--r-- 1 root root 514 Nov 27 11:52 Makefile
-rwxr-xr-x 1 root root 25843 Nov 27 12:03 tcps2-debug
-rwxr-xr-x 1 root root 4996 Nov 27 12:03 tcps2-release
-rw-r--r-- 1 root root 4554 Nov 27 11:52 tcps2.c
-rwxr-xr-x 1 root root 26823 Nov 27 12:03 tcpsp-debug
-rwxr-xr-x 1 root root 5396 Nov 27 12:03 tcpsp-release
-rw-r--r-- 1 root root 6164 Nov 27 11:55 tcpsp.c
[root@server11 1st_application]#
```

Two executable files, **tcps2-release** and **tcps2-debug**, are created.

tcps2-release—an ARM platform execution file (created specifically to run on the W311/321/341).

tcps2-debug—an ARM platform GDB debug server execution file (see Chapter 5 for details about the GDB debug tool).

NOTE If you get an error message at this point, it could be because you neglected to put **tcps2.c** and **tcpsp.c** in the same directory. The example Makefile we provide is set up to compile both **tcps2** and **tcpsp** into the same project Makefile. Alternatively, you could modify the Makefile to suit your particular requirements.

Uploading and Running the “tcps2-release” Program

Use the following commands to upload **tcps2-release** to the W311/321/341 through an FTP connection.

1. From the PC, type:

```
#ftp 192.168.3.127
```

2. Next, use the **bin** command to set the transfer mode to **Binary**, and the **put** command to initiate the file transfer:

```
ftp> bin
ftp> cd /home
ftp> put tcps2-release
```

```
root@server11:/home/w341/1st_application
```

```
[root@server11 1st_application]# ftp 192.168.3.127
Connected to 192.168.3.127 220
Moxa FTP server (Version wu-2.6.1(2) Mon Nov 24 12:17:04 CST 2003) ready.

694  nobody       3012  S    /usr/bin/httpd -k start -d /etc/apache
695  nobody       3012  S    /usr/bin/httpd -k start -d /etc/apache
696  nobody       3012  S    /usr/bin/httpd -k start -d /etc/apache
697  nobody       3012  S    /usr/bin/httpd -k start -d /etc/apache
698  nobody       3012  S    /usr/bin/httpd -k start -d /etc/apache
701  root          352  S    /bin/reportip
714  root        1176  S    -bash
726  root          436  S    /bin/telnetd
727  root         1164  S    -bash
728  root        1264  S    ./tcps2-release
729  root        1592  S    ps -ef
root@Moxa:~#

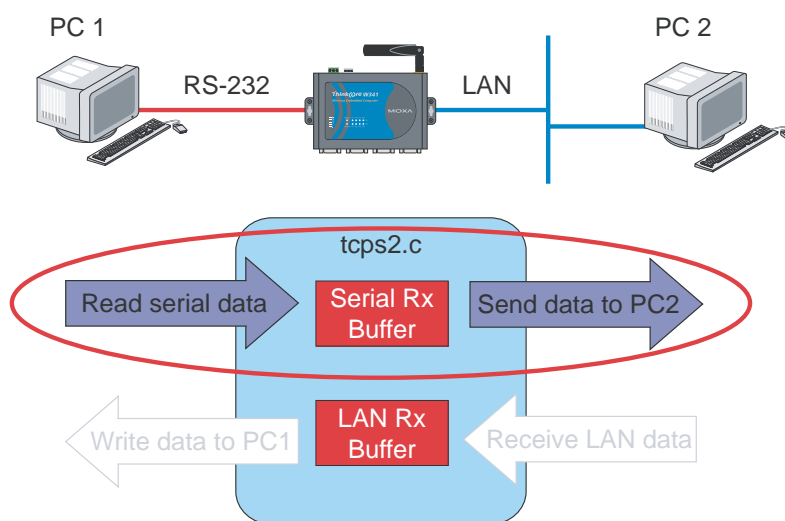

```

NOTE Use the `kill -9` command for PID 728 to terminate this program: `#kill -9 %728`

Testing Procedure Summary

1. Compile **tcps2.c** (**#make**).
2. Upload and run **tcps2-release** in the background (**#./tcps2-release &**).
3. Check that the process is running (**#jobs** or **#ps -ef**).
4. Use a serial cable to connect PC1 to the W311/321/341's serial port 1.
5. Use an Ethernet cable to connect PC2 to the W311/321/341.
6. On PC1: If running Windows, use HyperTerminal (**38400, n, 8, 1**) to open COMn.
7. On PC2: Type **#telnet 192.168.3.127 4001**.
8. On PC1: Type some text on the keyboard and then press **Enter**.
9. On PC2: The text you typed on PC1 will appear on PC2's screen.

The testing environment is illustrated in the following figure. However, note that there are limitations to the example program **tcps2.c**.

**NOTE**

The **tcps2.c** application is a simple example designed to give users a basic understanding of the concepts involved in combining Ethernet communication and serial port communication. However, the example program has some limitations that make it unsuitable for real-life applications.

1. The serial port is in canonical mode and block mode, making it impossible to send data from the Ethernet side to the serial side (i.e., from PC 2 to PC 1 in the above example).
2. The Ethernet side will not accept multiple connections.

Managing Embedded Linux

This chapter includes information about version control, deployment, updates, and peripherals. The information in this chapter will be particularly useful when you need to run the same application on several W311/321/341 units.

The following topics are covered in this chapter:

- ❑ **System Version Information**
- ❑ **System Image Backup**
 - Upgrading the Firmware
 - Loading Factory Defaults
 - Backing Up the User Directory
 - Deploying the User Directory to Additional W311/321/341 Units
- ❑ **Enabling and Disabling Daemons**
- ❑ **Setting the Run-Level**
- ❑ **Adjusting the System Time**
 - Setting the Time Manually
 - NTP Client
 - Updating the Time Automatically
- ❑ **Cron—Daemon to Execute Scheduled Commands**

System Version Information

To determine the hardware capability of your W311/321/341, and what kind of software functions are supported, check the version numbers of your W311/321/341's hardware, kernel, and user file system. Contact Moxa to determine the hardware version. You will need the Production S/N (Serial number), which is located on the W311/321/341's bottom label.

To check the kernel version, type:

#kversion

```
192.168.3.127 - PuTTY
root@Moxa:~#
kversion Version 1.0
root@Moxa:~#
```

NOTE The kernel version number is for the factory default configuration. You may download the latest firmware version from Moxa's website and then upgrade the W311/321/341's hardware.

System Image Backup

Upgrading the Firmware

The W311/321/341's bios, kernel, and root file system are combined into one firmware file, which can be downloaded from Moxa's website www.moxa.com). The name of the file has the form **w341-x.x.x.frm**, with "x.x.x" indicating the firmware version. To upgrade the firmware, download the firmware file to a PC, and then transfer the file to the W311/321/341 using a console port or Telnet console connection.

ATTENTION

Upgrading the firmware will erase all data on the Flash ROM

If you are using the ramdisk to store code for your applications, beware that updating the firmware will erase all of the data on the Flash ROM. You should back up your application files and data before updating the firmware.

Since different Flash disks have different sizes, it is a good idea to check the size of your Flash disk before upgrading the firmware, or before using the disk to store your application and data files. Use the **#df -h** command to list the size of each memory block and how much free space is available in each block.

```

192.168.3.127 - PuTTY
root@Moxa:~# df -h
Filesystem      Size  Used Available Use% Mounted on
/dev/mtdblock2  8.0M   6.0M    2.0M   75% /
/dev/ram0        499.0k  16.0k  458.0k    3% /var
/dev/mtdblock3   6.0M  488.0k   5.5M    8% /tmp
/dev/mtdblock3   6.0M  488.0k   5.5M    8% /home
/dev/mtdblock3   6.0M  488.0k   5.5M    8% /etc
tmpfs            30.4M     0   30.4M    0% /dev/shm
root@Moxa:~# upramdisk
root@Moxa:~# df -h
Filesystem      Size  Used Available Use% Mounted on
/dev/mtdblock2  8.0M   6.0M    2.0M   75% /
/dev/ram0        499.0k  16.0k  458.0k    3% /var
/dev/mtdblock3   6.0M  488.0k   5.5M    8% /tmp
/dev/mtdblock3   6.0M  488.0k   5.5M    8% /home
/dev/mtdblock3   6.0M  488.0k   5.5M    8% /etc
tmpfs            30.4M     0   30.4M    0% /dev/shm
/dev/ram1        16.0M   1.0k  15.1M    0% /mnt/ramdisk
root@Moxa:~# cd /mnt/ramdisk
root@Moxa:/mnt/ramdisk#

```

The following instructions give the steps required to save the firmware file to the W311/321/341's RAM disk and how to upgrade the firmware.

1. Type the following commands to enable the RAM disk:

```
#upramdisk
#cd /mnt/ramdisk
```

2. Type the following commands to use the W311/321/341's built-in FTP client to transfer the firmware file (W341-**x.x.x.frm**) from the PC to the W311/321/341:

```
/mnt/ramdisk> ftp <destination PC's IP> Login Name: xxxx
Login Password: xxxx
ftp> bin
ftp> get -x.x.x.frm
```

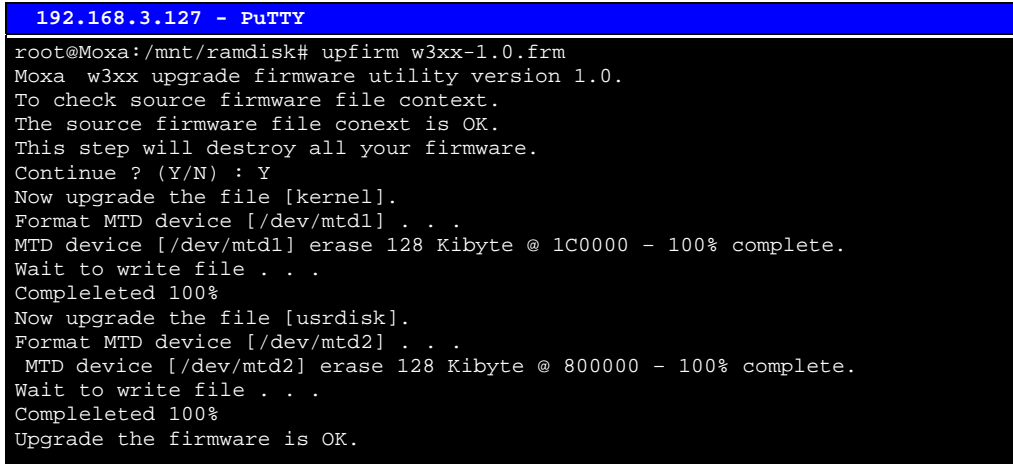

```

192.168.3.127 - PuTTY
root@Moxa:/mnt/ramdisk# ftp 192.168.3.193
Connected to 192.168.3.193 (192.168.3.193).
220 TYPSoft FTP Server 1.10 ready...
Name (192.168.3.193:root): root
331 Password required for root.
Password:
230 User root logged in.

ftp>

```

- Next, for W321 and W341, use the **upfirm** command to upgrade the kernel and root file system.

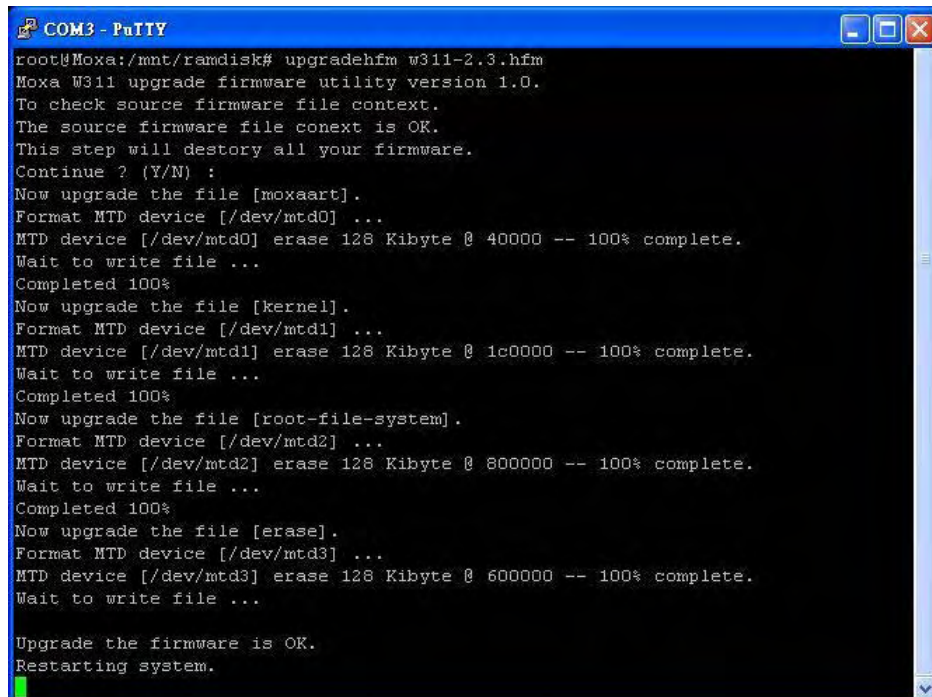

```
#upfirm w3xx-x.x.x.frm
```

```
192.168.3.127 - PuTTY
root@Moxa:/mnt/ramdisk# upfirm w3xx-1.0.frm
Moxa w3xx upgrade firmware utility version 1.0.
To check source firmware file context.
The source firmware file context is OK.
This step will destroy all your firmware.
Continue ? (Y/N) : Y
Now upgrade the file [kernel].
Format MTD device [/dev/mtd1] . . .
MTD device [/dev/mtd1] erase 128 Kibyte @ 1c0000 - 100% complete.
Wait to write file . . .
Completed 100%
Now upgrade the file [usrdisk].
Format MTD device [/dev/mtd2] . . .
MTD device [/dev/mtd2] erase 128 Kibyte @ 800000 - 100% complete.
Wait to write file . . .
Completed 100%
Upgrade the firmware is OK.
```

- For W311, use **upgradehfm** command to upgrade the kernel and root file system.

```
#upgradehfm w3xx-x.x.x.hfm
```

```
COM3 - PuTTY
root@Moxa:/mnt/ramdisk# upgradehfm w311-2.3.hfm
Moxa W311 upgrade firmware utility version 1.0.
To check source firmware file context.
The source firmware file context is OK.
This step will destroy all your firmware.
Continue ? (Y/N) : Y
Now upgrade the file [moxaart].
Format MTD device [/dev/mtd0] ...
MTD device [/dev/mtd0] erase 128 Kibyte @ 400000 -- 100% complete.
Wait to write file ...
Completed 100%
Now upgrade the file [kernel].
Format MTD device [/dev/mtd1] ...
MTD device [/dev/mtd1] erase 128 Kibyte @ 1c0000 -- 100% complete.
Wait to write file ...
Completed 100%
Now upgrade the file [root-file-system].
Format MTD device [/dev/mtd2] ...
MTD device [/dev/mtd2] erase 128 Kibyte @ 800000 -- 100% complete.
Wait to write file ...
Completed 100%
Now upgrade the file [erase].
Format MTD device [/dev/mtd3] ...
MTD device [/dev/mtd3] erase 128 Kibyte @ 600000 -- 100% complete.
Wait to write file ...

Upgrade the firmware is OK.
Restarting system.
```

ATTENTION

The upfirm utility will reboot your target after the upgrade is OK.

Loading Factory Defaults

To load the the factory default settings, you must press the reset-to-default button for more than 5 seconds. All files in the /home & /etc directories will be destroyed. Note that while pressing the reset-to-default button, the Ready LED will blink once every second for the first 5 seconds. The Ready LED will turn off after 5 seconds, and the factory defaults will be loaded.

Backing Up the User Directory

1. Create a backup file. First type the following command to enable the RAM disk:

```
#upramdisk
```

Next, use the file system backup utility provided by Moxa:

```
#backupuf /mnt/ramdisk/usrfs-backup
```

2. Once the file system is backed up, use FTP to transfer the file usrfs-backup to your PC.

```
192.168.3.127 - PuTTY
root@Moxa:~# upramdisk
root@Moxa:~# cd /mnt/ramdisk
root@Moxa:/mnt/ramdisk# df -h
Filesystem      Size      Used    Available  Use%    Mounted on
/dev/mtdblock2   8.0M       6.0M       2.0M       75%      /
/dev/ram0        499.0k     17.0k     457.0k       4%      /var

root@Moxa:/mnt/ramdisk# backupuf /mnt/ramdisk/usrfs-backup
Sync the file system...
Now backup the user root file system. Please wait. . .
. . . . .
Backup user root file system OK.
root@Moxa:/mnt/ramdisk#
```

Deploying the User Directory to Additional W311/321/341 Units

For some applications, you may need to ghost one W311/321/341 user file system to other W311/321/341 units. Back up the user file system to a PC (refer to the previous subsection, Backing Up the User File System, for instructions), and then type the following commands to copy the backup to additional W311/321/341 units.

```
#upramdisk
#cd /mnt/ramdisk
#upfirm usrfs-backup
```

```
192.168.3.127 - PuTTY
root@Moxa:/mnt/ramdisk# ls -al
drwxr-xr-x  3 root  root   1024 Jun 15 02:47
drwxr-xr-x 15 root  root     0 Sep 29 2004
-rw-----  1 root  root  12288 Jun 15 02:45  lost+found
-rw-r--r--  1 root  root 27263140 Jun 15 02:48  usrfs-backup
root@Moxa:/mnt/ramdisk# upfirm usrfs-backup
Moxa w3xx upgrade firmware utility version 1.0.
To check source firmware file context.
The source firmware file context is OK.
This step will destroy all your firmware.
Continue ? (Y/N) : Y
Now upgrade the file [userdisk]:
Format MTD device [/dev/mtd3] . . .
MTD device [/dev/mtd3] erase 128 Kibyte @ 600000 - 100% complete.
Wait to write file . . .
Completed 100%
Upgrade the firmware is OK.
```

Enabling and Disabling Daemons

The following daemons are enabled when the W311/321/341 unit boots up for the first time.

```
snmpd .....SNMP Agent daemon
telnetd .....Telnet Server / Client daemon
inetd .....Internet Daemons
ftpd.....FTP Server / Client daemon
sshd .....Secure Shell Server daemon
httpd.....Apache WWW Server daemon
```

Type the command “ps -ef” to list all processes currently running.

```

192.168.3.127 - PuTTY
root@Moxa:~# cd /etc
root@Moxa:/etc# ps -ef
  PID  Uid      VmSize  Stat  Command
    1  root         532  S    init [3]
    2  root          SWN  [ksoftirqd/0]
    3  root          SW<  [events/0]
    4  root          SW<  [khelper]
   13  root          SW<  [kblockd/0]
   14  root          SW    [khubd]

  714  root       1176  S    -bash
  726  root        436  S    /bin/telnetd
  727  root       1180  S    -bash
  783  root        628  R    ps -ef
root@Moxa:/ect#

```

To run a private daemon, you can edit the file rc.local, as follows:

```

#cd /etc/rc.d
#vi rc.local

```

```

192.168.3.127 - PuTTY
root@Moxa:~# cd /etc/rc.d
root@Moxa:~# /etc/rc.d# vi rc.local

```

Next, use vi to open your application program. We use the example program tcps2-release, and put it to run in the background.

```

192.168.3.127 - PuTTY
# !/bin/sh
# Add you want to run daemon
/home/tcps2-release &~

```

The enabled daemons will be available after you reboot the system.

```
192.168.3.127 - PuTTY
root@Moxa:~# ps -ef
  PID  Uid    VmSize  Stat Command
    1  root      532 S    init [3]
    2  root          SWN  [ksoftirqd/0]
    3  root          SW<  [events/0]

  685  root     1176 S    /bin/sh -login
  690  root      464 S    /bin/snmpd
  694  nobody    3012 S    /usr/bin/httpd -k start -d /etc/apache
  695  nobody    3012 S    /usr/bin/httpd -k start -d /etc/apache
  696  nobody    3012 S    /usr/bin/httpd -k start -d /etc/apache
  697  nobody    3012 S    /usr/bin/httpd -k start -d /etc/apache
  698  nobody    3012 S    /usr/bin/httpd -k start -d /etc/apache
  701  root      352 S    /bin/reportip
  714  root     1176 S    -bash
  726  root      436 S    /bin/telnetd
  727  root     1180 S    -bash
  783  root      628 R    ps -ef
root@Moxa:~#
```

Setting the Run-Level

In this section, we outline the steps you should take to set the Linux run-level and execute requests. Use the following command to enable or disable settings:

```
192.168.3.127 - PuTTY
root@Moxa:/etc/rc.d/rc3.d# ls
S19nfs-common S25nfs-user-server S99showreadyled
S20snmpd S55ssh
S24pcmcia S99rmnologin
root@Moxa:/etc/rc.d/rc3.d#
```

```
#cd /etc/rc.d/init.d
```

Edit a shell script to execute /home/tcps2-release and save to tcps2 as an example.

```
#cd /etc/rc.d/rc3.d
```

```
#ln -s /etc/rc.d/init.d/tcps2 S60tcps2
```

SxxRUNFILE stands for

S: start the run file while linux boots up.

xx: a number between 00-99. Smaller numbers have a higher priority.

RUNFILE: the file name.

```

192.168.3.127 - PuTTY
root@Moxa:/etc/rc.d/rc3.d# ls
S19nfs-common S25nfs-user-server S99showreadyled
S20snmpd S55ssh
S24pcmcia S99rmnologin
root@Moxa:/etc/rc.d/rc3.d# ln -s /home/tcps2-release S60tcps2
root@Moxa:/etc/rc.d/rc3.d# ls
S19nfs-common S25nfs-user-server S99rmnologin
S20snmpd S55ssh S99showreadyled
S24pcmcia S60tcps2
root@Moxa:/etc/rc.d/rc3.d# █

```

KxxRUNFILE stands for

K: start the run file while linux shuts down or halts.

xx: a number between 00-99. Smaller numbers have a higher priority.

RUNFILE: the file name.

To remove the daemon, remove the run file from the /etc/rc.d/rc3.d directory by using the following command:

```
#rm -f /etc/rc.d/rc3.d/S60tcps2
```

Adjusting the System Time

Setting the Time Manually

The W311/321/341 have two time settings. One is the system time, and the other is the RTC (Real Time Clock) time kept by the W311/321/341's hardware. Use the #date command to query the current system time or set a new system time. Use #hwclock to query the current RTC time or set a new RTC time.

Use the following command to query the system time:

```
#date
```

Use the following command to query the RTC time:

```
#hwclock
```

Use the following command to set the system time:

```
#date MMDDhhmmYYYY
```

MM = Month

DD = Date

hhmm = hour and minute

YYYY = Year

Use the following command to set the RTC time:

```
#hwclock -w
```

Write current system time to RTC

The following figure illustrates how to update the system time and set the RTC time.

```
192.168.3.127 - PuTTY
root@Moxa:~# date
Fri Jun 23 23:30:31 CST 2000
root@Moxa:~# hwclock
Fri Jun 23 23:30:35 2000 -0.557748 seconds
root@Moxa:~# date 120910002004
Thu Dec 9 10:00:00 CST 2004
root@Moxa:~# hwclock -w
root@Moxa:~# date ; hwclock
Thu Dec 9 10:01:07 CST 2004
Thu Dec 9 10:01:08 2004 -0.933547 seconds
root@Moxa:~#
```

NTP Client

The W311/321/341 have a built-in NTP (Network Time Protocol) client that is used to initialize a time request to a remote NTP server. Use `#ntpdate <this client utility>` to update the system time.

```
#ntpdate time.stdtime.gov.tw
#hwclock -w
```

Visit <http://www.ntp.org> for more information about NTP and NTP server addresses.

```
10.120.53.100 - PuTTY
root@Moxa:~# date ; hwclock
Sat Jan 1 00:00:36 CST 2000
Sat Jan 1 00:00:37 2000 -0.772941 seconds
root@Moxa:~# ntpdate time.stdtime.gov.tw
9 Dec 10:58:53 ntpdate[207]: step time server 220.130.158.52 offset 155905087.984256
sec
root@Moxa:~# hwclock -w
root@Moxa:~# date ; hwclock
Thu Dec 9 10:59:11 CST 2004
Thu Dec 9 10:59:12 2004 -0.844076 seconds
root@Moxa:~#
```

NOTE Before using the NTP client utility, check your IP and DNS settings to make sure that an Internet connection is available. Refer to Chapter 2 for instructions on how to configure the Ethernet interface, and see Chapter 4 for DNS setting information.

Updating the Time Automatically

In this subsection, we show how to use a shell script to update the time automatically.

Example shell script to update the system time periodically

```
#!/bin/sh
ntpdate time.nist.gov
# You can use the time server's ip address or domain
# name directly. If you use domain name, you must
# enable the domain client on the system by updating
# /etc/resolv.conf file.
hwclock --systohc
sleep 100
# Updates every 100 seconds. The min. time is 100 seconds. Change
# 100 to a larger number to update RTC less often.
```

Save the shell script using any file name. E.g., `fixtime`

How to run the shell script automatically when the kernel boots up

Copy the example shell script `fixtime` to directory `/etc/init.d`, and then use `chmod 755 fixtime` to change the shell script mode. Next, use `vi` editor to edit the file `/etc/inittab`. Add the following line to the bottom of the file:

```
ntp : 2345 : respawn : /etc/init.d/fixtime
```

Use the command `#init q` to re-init the kernel.

Cron—Daemon to Execute Scheduled Commands

Start Cron from the directory `/etc/rc.d/rc.local`. It will return immediately, so you don't need to start it with `'&'` to run in the background.

The Cron daemon will search `/etc/cron.d/crontab` for crontab files, which are named after accounts in `/etc/passwd`.

Cron wakes up every minute, and checks each command to see if it should be run in that minute. Modify the file `/etc/cron.d/crontab` to set up your scheduled applications. Crontab files have the following format:

mm	h	dom	mon	dow	user	command
min	hour	date	month	week	user	command
0-59	0-23	1-31	1-12	0-6 (0 is Sunday)		

The following example demonstrates how to use Cron.

How to use cron to update the system time and RTC time every day at 8:00.

STEP1: Write a shell script named `fixtime.sh` and save it to `/home/`.

```
#!/bin/sh
ntpdate time.nist.gov
hwclock --systohc
exit 0
```

STEP2: Change mode of `fixtime.sh`

```
#chmod 755 fixtime.sh
```

STEP3: Modify `/etc/cron.d/crontab` file to run `fixtime.sh` at 8:00 every day.

Add the following line to the end of crontab:

```
* 8 * * * root/homefixtime.sh
```

STEP4: Enable the cron daemon manually.

```
#!/etc/init.d/cron start
```

STEP5: Enable cron when the system boots up.

Add the following line in the file `/etc/init.d/rc.local`

```
#!/etc/init.d/cron start
```

Managing Communications

In this chapter, we explain how to configure the W311/321/341's various communication functions.

The following topics are covered in this chapter:

- ☐ **Telnet / FTP**
- ☐ **DNS**
- ☐ **Web Service—Apache**
- ☐ **Installing PHP for Apache Web Server**
- ☐ **IPTABLES**
- ☐ **NAT**
 - NAT Example
 - Enabling NAT at Bootup
- ☐ **Dial-up Service—PPP**
- ☐ **PPPoE**
- ☐ **NFS (Network File System)**
 - Setting up the W311/321/341 as an NFS Client
- ☐ **Mail**
- ☐ **SNMP**
- ☐ **OpenVPN**

Telnet / FTP

In addition to supporting Telnet client/server and FTP client/server, the W311/321/341 also support SSH and sftp client/server. To enable or disable the Telnet/ftp server, you first need to edit the file `/etc/inetd.conf`.

Enabling the Telnet/ftp server

The following example shows the default content of the file `/etc/inetd.conf`. The default is to enable the Telnet/ftp server:

```
discard dgram udp wait root /bin/discard
discard stream tcp nowait root /bin/discard
telnet stream tcp nowait root /bin/telnetd
ftp stream tcp nowait root /bin/ftpd -l
```

Disabling the Telnet/ftp server

Disable the daemon by typing '#' in front of the first character of the row to comment out the line.

DNS

The W311/321/341 support DNS client (but not DNS server). To set up DNS client, you need to edit three configuration files: `/etc/hosts`, `/etc/resolv.conf`, and `/etc/nsswitch.conf`.

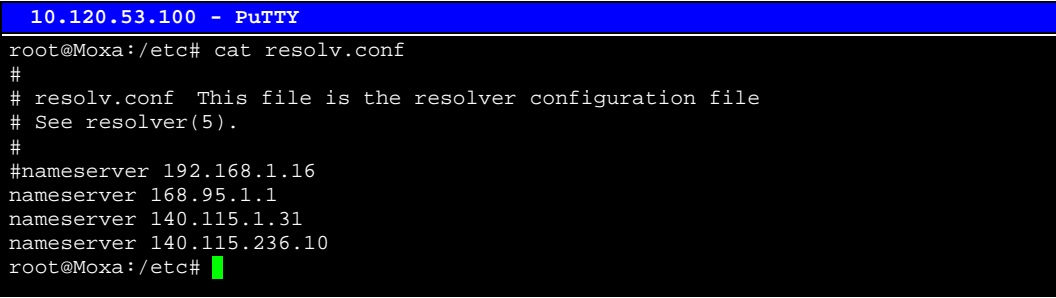

`/etc/hosts`

This is the first file that the Linux system reads to resolve the host name and IP address.

`/etc/resolv.conf`

This is the most important file that you need to edit when using DNS for the other programs. For example, before you use `#ntpdate time.nist.gov` to update the system time, you will need to add the DNS server address to the file. Ask your network administrator which DNS server address you should use. The DNS server's IP address is specified with the "nameserver" command. For example, add the following line to `/etc/resolv.conf` if the DNS server's IP address is 168.95.1.1:

```
nameserver 168.95.1.1
```

A screenshot of a terminal window with a blue title bar that reads "10.120.53.100 - PuTTY". The terminal shows a root user at a Moxa machine in the /etc directory. The user has entered the command "cat resolv.conf", and the output shows the contents of the file. The file contains several comments and four nameserver entries. The last entry is "nameserver 168.95.1.1". The prompt "root@Moxa:/etc#" is visible at the bottom of the terminal, followed by a green cursor.

```
10.120.53.100 - PuTTY
root@Moxa:/etc# cat resolv.conf
#
# resolv.conf This file is the resolver configuration file
# See resolver(5).
#
#nameserver 192.168.1.16
nameserver 168.95.1.1
nameserver 140.115.1.31
nameserver 140.115.236.10
root@Moxa:/etc#
```

`/etc/nsswitch.conf`

This file defines the sequence to resolve the IP address by using `/etc/hosts` file or `/etc/resolv.conf`.

Web Service—Apache

The Apache web server's main configuration file is `/etc/apache/conf/httpd.conf`, with the default homepage located at `/home/httpd/htdocs/index.html`. Save your own homepage to the following directory:

`/home/httpd/htdocs/`

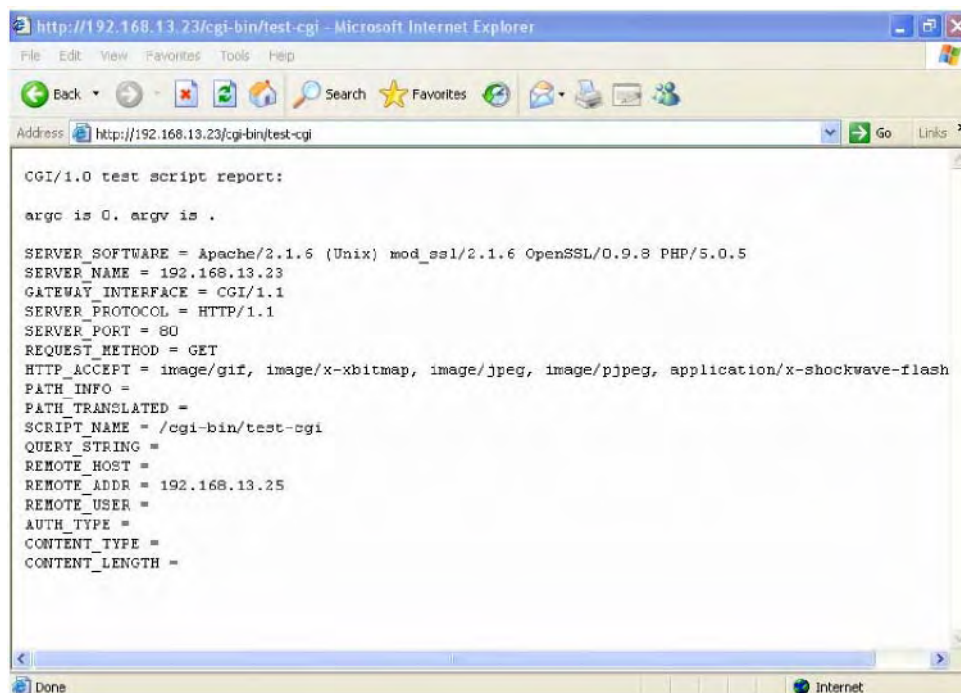

Save your CGI page to the following directory:

`/home/httpd/cgi-bin/`

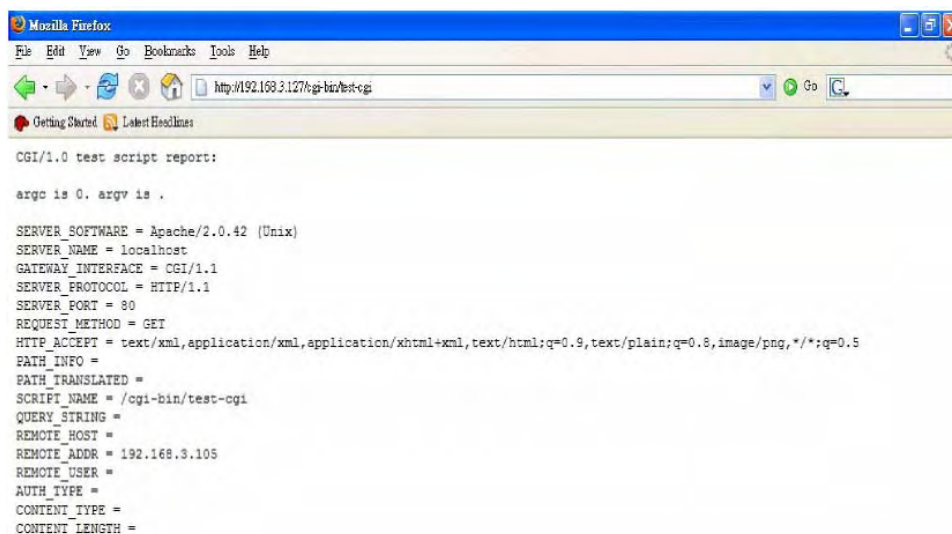

Before you modify the homepage, use a browser (such as Microsoft Internet Explorer or Mozilla Firefox) from your PC to test if the Apache Web Server is working. Type the LAN1 IP address in the browser's address box to open the homepage. E.g., if the default IP address is still active, type **`http://192.168.3.127`** in the address box.

To open the default CGI page, type **`http://192.168.3.127/cgi-bin/test-cgi`** in your browser's address box.

To open the default CGI test script report page, type **http://192.168.3.127/cgi-bin/test-cgi** in your browser's address box.

NOTE The CGI function is enabled by default. If you want to disable the function, modify the file **/etc/apache/conf/httpd.conf**. When you develop your own CGI application, make sure your CGI file is executable.

```

192.168.3.127 - PuTTY
root@Moxa:/home/httpd/cgi-bin# ls -al
drwxr-xr-x  2 root root      0 Aug 24 1999
drwxr-xr-x  5 root root      0 Nov  5 16:16
-rwxr-xr-x  1 root root 757 Aug 24 1999 test-cgi
root@Moxa:/home/httpd/cgi-bin#
  
```

Installing PHP for Apache Web Server

This embedded computer supports the PHP option. However, since the PHP file is 3 MB, it is not installed by default. To install it yourself, first make sure there is enough free space (at least 3 MB) on your embedded flash ROM).

Step 1: Check that you have enough free space

```

192.168.3.127 - PuTTY
root@Moxa:/bin# df -h
Filesystem      Size      Used Available Use% Mounted on
/dev/mtdblock2  8.0M       6.0M      2.0M   75% /
/dev/ram0       499.0k     17.0k    457.0k    4% /var
/dev/mtdblock3  6.0M     488.0k    5.5M    8% /tmp
/dev/mtdblock3  6.0M     488.0k    5.5M    8% /home
/dev/mtdblock3  6.0M     488.0k    5.5M    8% /etc
tmpfs           30.4M        0     30.4M    0% /dev/shm
root@Moxa:/bin#
  
```

To check that the **/dev/mtdblock3** free space is greater than 3 MB.

Step 2: Type “upramdisk” to get the free space ram disk to save the package.

```
192.168.3.127 - PuTTY
root@Moxa:/bin# upramdisk
root@Moxa:/bin# df -h
Filesystem                Size      Used Available Use% Mounted on
/dev/mtdblock2             8.0M        6.0M       2.0M  75% /
/dev/ram0                  499.0k      18.0k     456.0k   4% /var
/dev/mtdblock3             6.0M      488.0k     5.5M   8% /tmp
/dev/mtdblock3             6.0M      488.0k     5.5M   8% /home
/dev/mtdblock3             6.0M      488.0k     5.5M   8% /etc
tmpfs                     30.4M         0      30.4M   0% /dev/shm
/dev/ram1                  16.0M        1.0k     15.1M   0% /var/ramdisk
root@Moxa:/bin#
```

Step 3: Download the PHP package from the CD-ROM. You can find the package in CD-ROM/target/php/php.tar.gz

```
192.168.3.127 - PuTTY
root@Moxa:/bin# cd /mnt/ramdisk
root@Moxa:/mnt/ramdisk# ftp 192.168.27.130
Connected to 192.168.27.130.
220 (vsFTPd 2.0.1)
Name (192.168.27.130:root):
root 331 Please specify the password.
Password:
230 Login successful.
Remote system type is UNIX.
Using binary mode to transfer files.
ftp> cd /tmp
250 Directory successfully changed.
ftp> bin
200 Switching to Binary mode.
ftp> get php.tar.gz
local: php.tar.gz remote: php.tar.gz
200 PORT command successful. Consider using PASV.
150 Opening BINARY mode data connection for php.tar.gz (1789032 bytes).
226 File send OK.
1789032 bytes received in 0.66 secs (2.6e+03 Kbytes/sec)
ftp>
```

Step 4: uhtar the package. To do this, type the command “tar xvzf php.tar.gz”.

```
192.168.3.127 - PuTTY
root@Moxa:/mnt/ramdisk# tar xvzf php.tar.gz
envvars
envvars.old
httpd.conf
httpd.conf.old
install.sh
lib
lib/libmysqlclient.so.15
lib/libpng.so.2
lib/libphp5.so
lib/libmysqlclient.so.15.0.0
lib/libgd.so
lib/libxml2.so.2.6.22
lib/libgd.so.2.0.0
lib/libjpeg.so
lib/libxml2.so.2
lib/libgd.so.2
php
php/php.ini
phpinfo.php
root@Moxa:/mnt/ramdisk#
```

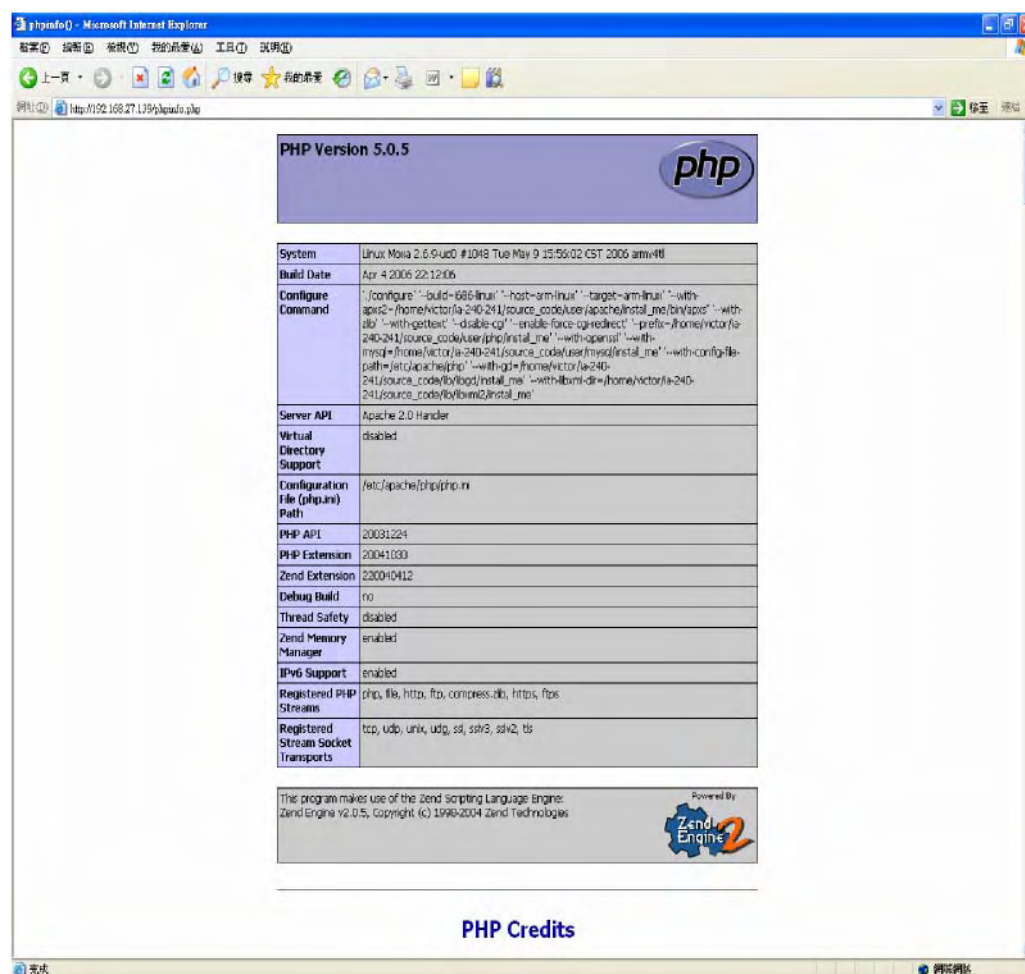

Step 5: Run “install.sh” and select to install php.

```

192.168.3.127 - PuTTY
root@Moxa:/mnt/ramdisk# ./install.sh
Press the number:
1. Install PHP package
2. Uninstall PHP package
3. Exit.
1
Start to install PHP. Please wait ...
Starting web server: apache.
PHP install success.
root@Moxa:/mnt/ramdisk#

```

Step 6: Test it. Use the browser to access <http://192.168.3.127/phpinfo.php>.

If you want to uninstall PHP, follow steps 2 to 5 but select the uninstall option.

IPTABLES

IPTABLES is an administrative tool for setting up, maintaining, and inspecting the Linux kernel's IP packet filter rule tables. Several different tables are defined, with each table containing built-in chains and user-defined chains.

Each chain is a list of rules that apply to a certain type of packet. Each rule specifies what to do with a matching packet. A rule (such as a jump to a user-defined chain in the same table) is called a "target."

The W311/321/341 support 3 types of IPTABLES table: **Filter** tables, **NAT** tables, and **Mangle** tables:

A. Filter Table—includes three chains:

- INPUT chain
- OUTPUT chain
- FORWARD chain

B. NAT Table—includes three chains:

- PREROUTING chain—transfers the destination IP address (DNAT)
- POSTROUTING chain—works after the routing process and before the Ethernet device process to transfer the source IP address (SNAT)
- OUTPUT chain—produces local packets

sub-tables

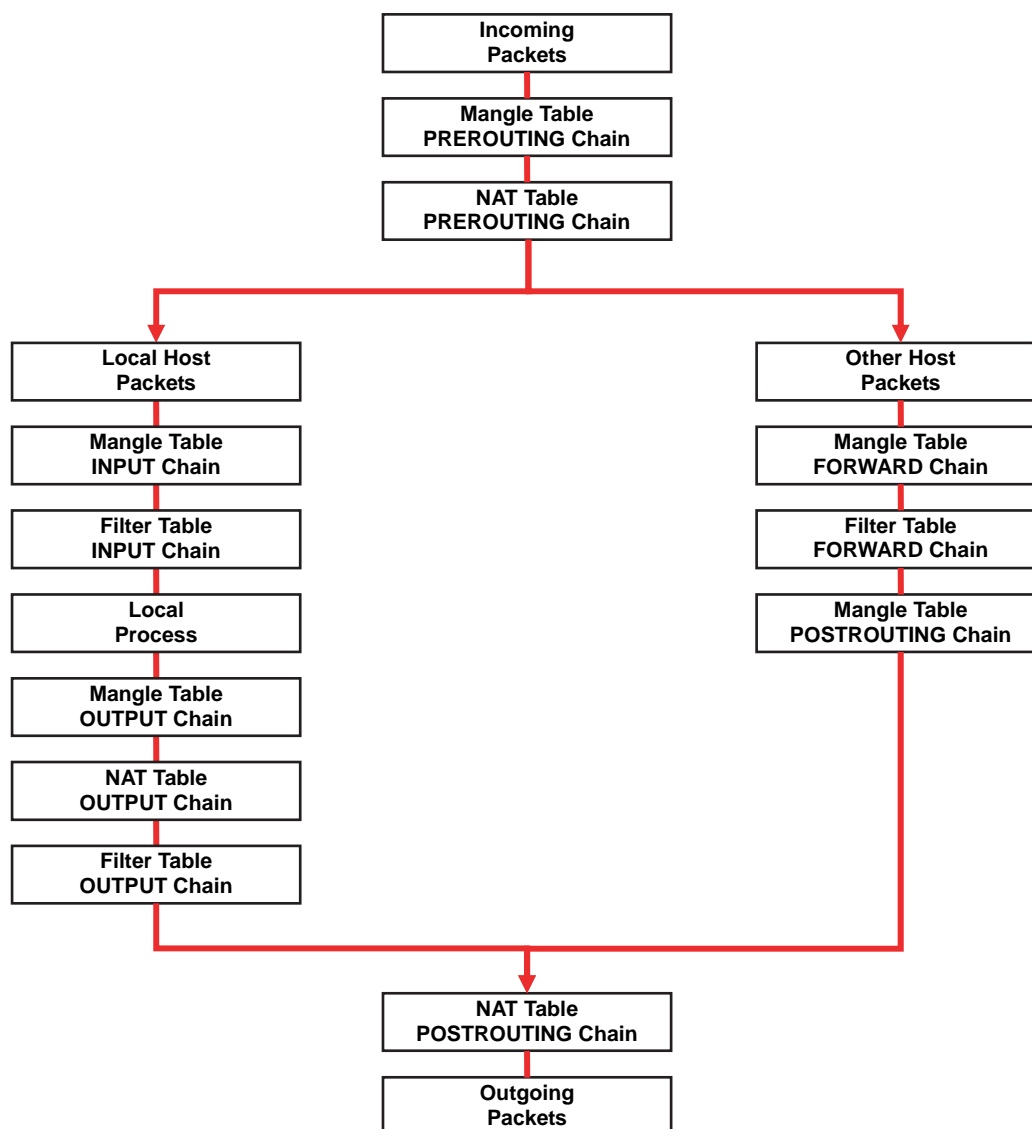

- Source NAT (SNAT)—changes the first source packet IP address
- Destination NAT (DNAT)—changes the first destination packet IP address
- MASQUERADE—a special form for SNAT. If one host can connect to Internet, then other computers that connect to this host can connect to the Internet when the computer does not have an actual IP address.
- REDIRECT—a special form of DNAT that re-sends packets to a local host independent of the destination IP address.

C. Mangle Table—includes two chains

- PREROUTING chain—pre-processes packets before the routing process.
- OUTPUT chain—processes packets after the routing process.

It has three extensions—TTL, MARK, TOS.

The following figure shows the IPTABLES hierarchy.

The W311/321/341 support the following sub-modules. Be sure to use the module that matches your application.

ip_conntrack	ipt_MARK	ipt_ah	ipt_state
ip_conntrack_ftp	ipt_MASQUERADE	ipt_esp	ipt_tcpmss
ipt_conntrack_irc	ipt_MIRROT	ipt_length	ipt_tos
ip_nat_ftp	ipt_REDIRECT	ipt_limit	ipt_ttl
ip_nat_irc	ipt_REJECT	ipt_mac	ipt_unclean
ip_nat_snmp_basic	ipt_TCPMSS	ipt_mark	
ip_queue	ipt_TOS	ipt_multiport	
ipt_LOG	ipt_ULOG	ipt_owner	

NOTE The W311/321/341 do NOT support IPV6 and ipchains.

The basic syntax to enable and load an IPTABLES module is as follows:

```
#lsmod
#insmod ip_tables
#insmod iptable_filter
```

Use lsmod to check if the ip_tables module has already been loaded in the W311/321/341 unit.
Use insmod to insert and enable the module.

Use the following command to load the modules (iptables_filter, iptable_mangle, iptable_nat):

```
#insmod iptable_filter
```

NOTE IPTABLES plays the role of packet filtering or NAT. Take care when setting up the IPTABLES rules. If the rules are not correct, remote hosts that connect via a LAN or PPP may be denied access. We recommend using the serial console to set up the IPTABLES.

Click on the following links for more information about iptables.

<http://www.linuxguruz.com/iptables/>

<http://www.netfilter.org/documentation/HOWTO//packet-filtering-HOWTO.html>

Since the IPTABLES command is very complex, to illustrate the IPTABLES syntax we have divided our discussion of the various rules into three categories: **Observe and erase chain rules**, **Define policy rules**, and **Append or delete rules**.

Observe and erase chain rules

Usage:

```
# iptables [-t tables] [-L] [-n]
```

-t tables: Table to manipulate (default: 'filter'); example: nat or filter.

-L [chain]: List List all rules in selected chains. If no chain is selected, all chains are listed.

-n: Numeric output of addresses and ports.

```
# iptables [-t tables] [-FXX]
```

-F: Flush the selected chain (all the chains in the table if none is listed).

-X: Delete the specified user-defined chain.

-Z: Set the packet and byte counters in all chains to zero.

Examples:

```
# iptables -L -n
```

In this example, since we do not use the -t parameter, the system uses the default 'filter' table. Three chains are included: INPUT, OUTPUT, and FORWARD. INPUT chains are accepted automatically, and all connections are accepted without being filtered.

```
#iptables -F
#iptables -X
#iptables -Z
```

Define policy for chain rules

Usage:

```
# iptables [-t tables] [-P] [INPUT, OUTPUT, FORWARD, PREROUTING, OUTPUT, POSTROUTING]
[ACCEPT, DROP]
```

-P: Set the policy for the chain to the given target.
 INPUT: For packets coming into the W311/321/341.
 OUTPUT: For locally-generated packets.
 FORWARD: For packets routed out through the W311/321/341.
 PREROUTING: To alter packets as soon as they come in.
 POSTROUTING: To alter packets as they are about to be sent out.

Examples:

```
#iptables -P INPUT DROP
#iptables -P OUTPUT ACCEPT
#iptables -P FORWARD ACCEPT
#iptables -t nat -P PREROUTING ACCEPT
#iptables -t nat -P OUTPUT ACCEPT
#iptables -t nat -P POSTROUTING ACCEPT
```

In this example, the policy accepts outgoing packets and denies incoming packets.

Append or delete rules

Usage:

```
# iptables [-t table] [-AI] [INPUT, OUTPUT, FORWARD] [-i interface] [-p tcp, udp, icmp,
all] [-s IP/network] [--sport ports] [-d IP/network] [--dport ports] -j [ACCEPT, DROP]
```

-A: Append one or more rules to the end of the selected chain.
 -I: Insert one or more rules in the selected chain as the given rule number.
 -i: Name of an interface via which a packet is going to be received.
 -o: Name of an interface via which a packet is going to be sent.
 -p: The protocol of the rule or of the packet to check.
 -s: Source address (network name, host name, network IP address, or plain IP address).
 --sport: Source port number.
 -d: Destination address.
 --dport: Destination port number.
 -j: Jump target. Specifies the target of the rules; i.e., how to handle matched packets. For example, ACCEPT the packet, DROP the packet, or LOG the packet.

Examples:

Example 1: Accept all packets from lo interface.

```
# iptables -A INPUT -i lo -j ACCEPT
```

Example 2: Accept TCP packets from 192.168.0.1.

```
# iptables -A INPUT -i eth0 -p tcp -s 192.168.0.1 -j ACCEPT
```

Example 3: Accept TCP packets from Class C network 192.168.1.0/24.

```
# iptables -A INPUT -i eth0 -p tcp -s 192.168.1.0/24 -j ACCEPT
```

Example 4: Drop TCP packets from 192.168.1.25.

```
# iptables -A INPUT -i eth0 -p tcp -s 192.168.1.25 -j DROP
```

Example 5: Drop TCP packets addressed for port 21.

```
# iptables -A INPUT -i eth0 -p tcp --dport 21 -j DROP
```

Example 6: Accept TCP packets from 192.168.0.24 to W341's port 137, 138, 139

```
# iptables -A INPUT -i eth0 -p tcp -s 192.168.0.24 --dport 137:139 -j ACCEPT
```

Example 7: Drop all packets from MAC address 01:02:03:04:05:06.

```
# iptables -A INPUT -i eth0 -p all -m mac --mac-source 01:02:03:04:05:06 -j DROP
```

NOTE: In Example 7, remember to issue the command `#insmod ipt_mac` first to load module `ipt_mac`.

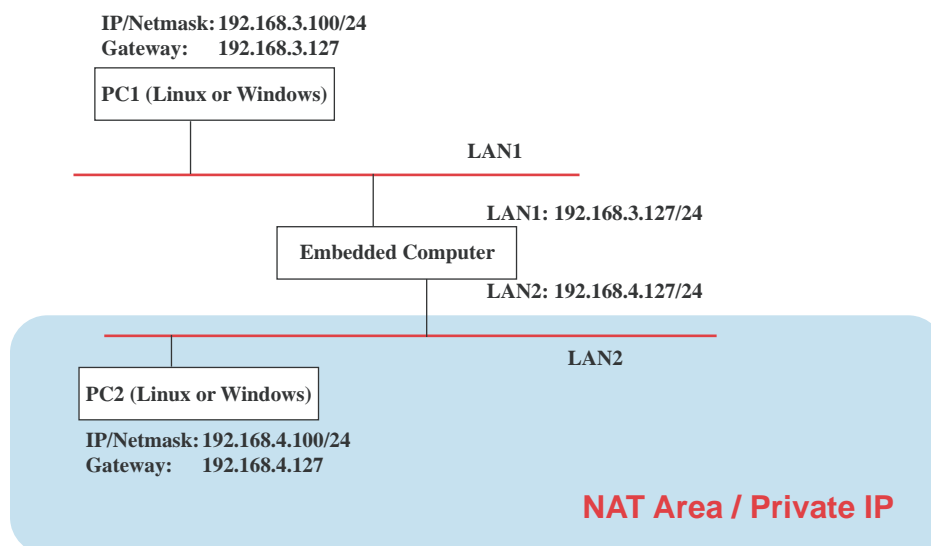

NAT

NAT (Network Address Translation) protocol translates IP addresses used on one network to different IP addresses used on another network. One network is designated the inside network and the other is the outside network. Typically, the W311/321/341 connect several devices on a network and maps local inside network addresses to one or more global outside IP addresses, and un-maps the global IP addresses on incoming packets back into local IP addresses.

NOTE Click on the following links for more information about iptables and NAT:
<http://www.netfilter.org/documentation/HOWTO/NAT-HOWTO.html>

NAT Example

The IP address of LAN1 is changed to 192.168.3.127 (you will need to load the module `ipt_MASQUERADE`):

```

1. #echo 1 > /proc/sys/net/ipv4/ip_forward
2. #insmod ip_tables
3. #insmod iptable_filter
4. #insmod ip_conntrack
5. #insmod iptable_nat
6. #insmod ipt_MASQUERADE
7. #iptables -t nat -A POSTROUTING -o eth0 -j SNAT --to-source 192.168.3.127
8. #iptables -t nat -A POSTROUTING -o eth0 -s 192.168.3.0/24 -j MASQUERADE
  
```

Enabling NAT at Bootup

In most real world situations, you will want to use a simple shell script to enable NAT when the W341 boots up. The following script is an example.

```
#!/bin/bash
# If you put this shell script in the /home/nat.sh
# Remember to chmod 744 /home/nat.sh
# Edit the rc.local file to make this shell startup automatically.
# vi /etc/rc.d/rc.local
# Add a line in the end of rc.local /home/nat.sh
EXIF='eth0' #This is an external interface for setting up a valid IP address.
EXNET='192.168.4.0/24' #This is an internal network address.
# Step 1. Insert modules.
# Here 2> /dev/null means the standard error messages will be dump to null device.
insmod ip_tables 2> /dev/null
insmod ip_conntrack 2> /dev/null
insmod ip_conntrack_ftp 2> /dev/null
insmod ip_conntrack_irc 2> /dev/null
insmod iptable_nat 2> /dev/null
insmod ip_nat_ftp 2> /dev/null
insmod ip_nat_irc 2> /dev/null
# Step 2. Define variables, enable routing and erase default rules.
PATH=/bin:/sbin:/usr/bin:/usr/sbin:/usr/local/bin:/usr/local/sbin
export PATH
echo "1" > /proc/sys/net/ipv4/ip_forward
/bin/iptables -F
/bin/iptables -X
/bin/iptables -Z
/bin/iptables -F -t nat
/bin/iptables -X -t nat
/bin/iptables -Z -t nat
/bin/iptables -P INPUT ACCEPT
/bin/iptables -P OUTPUT ACCEPT
/bin/iptables -P FORWARD ACCEPT
/bin/iptables -t nat -P PREROUTING ACCEPT
/bin/iptables -t nat -P POSTROUTING ACCEPT
/bin/iptables -t nat -P OUTPUT ACCEPT
# Step 3. Enable IP masquerade.
```

Dial-up Service—PPP

PPP (Point to Point Protocol) is used to run IP (Internet Protocol) and other network protocols over a serial link. PPP can be used for direct serial connections (using a null-modem cable) over a Telnet link, and links established using a modem over a telephone line.

Modem / PPP access is almost identical to connecting directly to a network through the W311/321/341's Ethernet port. Since PPP is a peer-to-peer system, the W311/321/341 can also use PPP to link two networks (or a local network to the Internet) to create a Wide Area Network (WAN).

NOTE	Click on the following links for more information about ppp: http://tldp.org/HOWTO/PPP-HOWTO/index.html http://axion.physics.ubc.ca/ppp-linux.html
------	--

The `pppd` daemon is used to connect to a PPP server from a Linux system. For detailed information about `pppd` see the man page.

Example 1: Connecting to a PPP server over a simple dial-up connection

The following command is used to connect to a PPP server by modem. Use this command for old ppp servers that prompt for a login name (replace username with the correct name) and password (replace password with the correct password). Note that `debug` and `defaultroute` 192.1.1.17 are optional.

```
#pppd connect 'chat -v " " ATDT5551212 CONNECT " " ogin: username word: password'
/dev/ttyM0 115200 debug crtscts modem defaultroute
```

If the PPP server does not prompt for the username and password, the command should be entered as follows. Replace username with the correct username and replace password with the correct password.

```
#pppd connect 'chat -v " " ATDT5551212 CONNECT " ""user username password password
/dev/ttyM0 115200 crtscts modem
```

The `pppd` options are described below:

```
connect 'chat etc...'
```

This option gives the command to contact the PPP server. The 'chat' program is used to dial a remote computer. The entire command is enclosed in single quotes because `pppd` expects a one-word argument for the 'connect' option. The options for 'chat' are given below:

```
-v
```

verbose mode; log what we do to syslog

```
" "
```

Double quotes—don't wait for a prompt, but instead do ... (note that you must include a space after the second quotation mark)

```
ATDT5551212
```

Dial the modem, and then ...

```
CONNECT
```

Wait for an answer.

```
" "
```

Send a return (null text followed by the usual return)

```
ogin: username word: password
```

Log in with username and password.

Refer to the chat man page, chat.8, for more information about the chat utility.

```
/dev/
```

Specify the callout serial port.

```
115200
```

The baudrate.

```
debug
```

Log status in syslog.

```
crtscts
```

Use hardware flow control between computer and modem (at 115200 this is a must).

modem

Indicates that this is a modem device; pppd will hang up the phone before and after making the call.

defaultroute

Once the PPP link is established, make it the default route; if you have a PPP link to the Internet, this is probably what you want.

192.1.1.17

This is a degenerate case of a general option of the form `x.x.x.x:y.y.y.y`. Here `x.x.x.x` is the local IP address and `y.y.y.y` is the IP address of the remote end of the PPP connection. If this option is not specified, or if just one side is specified, then `x.x.x.x` defaults to the IP address associated with the local machine's hostname (located in `/etc/hosts`), and `y.y.y.y` is determined by the remote machine.

Example 2: Connecting to a PPP server over a hard-wired link

If a username and password are not required, use the following command (note that `noipdefault` is optional):

```
#pppd connect 'chat -v " " " " ' noipdefault /dev/ttyM0 19200 crtscts "
```

If a username and password is required, use the following command (note that `noipdefault` is optional, and `root` is both the username and password):

```
#pppd connect 'chat -v " " " " ' user root password root noipdefault /dev/ttyM0 19200 crtscts
```

How to check the connection

Once you've set up a PPP connection, there are some steps you can take to test the connection. First, type:

```
/sbin/ifconfig
```

(The folder **ifconfig** may be located elsewhere, depending on your distribution.) You should be able to see all the network interfaces that are UP. `ppp0` should be one of them, and you should recognize the first IP address as your own, and the "P-t-P address" (or point-to-point address) the address of your server. Here's what it looks like on one machine:

```
lo      Link encap Local Loopback
        inet addr 127.0.0.1      Bcast 127.255.255.255      Mask 255.0.0.0
        UP LOOPBACK RUNNING      MTU 2000      Metric 1
        RX packets 0 errors 0 dropped 0 overrun 0

ppp0    Link encap Point-to-Point Protocol
        inet addr 192.76.32.3      P-t-P 129.67.1.165      Mask 255.255.255.0
        UP POINTOPOINT RUNNING    MTU 1500      Metric 1
        RX packets 33 errors 0 dropped 0 overrun 0
        TX packets 42 errors 0 dropped 0 overrun 0
```

Now, type:

```
ping z.z.z.z
```

where `z.z.z.z` is the address of your name server. This should work. Here's what the response could look like:

```
waddington:~$p ping 129.67.1.165
PING 129.67.1.165 (129.67.1.165): 56 data bytes
64 bytes from 129.67.1.165: icmp_seq=0 ttl=225 time=268 ms
64 bytes from 129.67.1.165: icmp_seq=1 ttl=225 time=247 ms
```

```
64 bytes from 129.67.1.165: icmp_seq=2 ttl=225 time=266 ms
```

```
^C
```

```
--- 129.67.1.165 ping statistics ---
```

```
3 packets transmitted, 3 packets received, 0% packet loss
```

```
round-trip min/avg/max = 247/260/268 ms
```

```
waddington:~$
```

Try typing:

```
netstat -nr
```

This should show three routes, something like this:

Kernel routing table

Destination	iface	Gateway	Genmask	Flags	Metric	Ref	Use
129.67.1.165	ppp0	0.0.0.0	255.255.255.255	UH	0	0	6
127.0.0.0		0.0.0.0	255.0.0.0	U	0	0	0 lo
0.0.0.0	ppp0	129.67.1.165	0.0.0.0	UG	0	0	6298

If your output looks similar but doesn't have the destination 0.0.0.0 line (which refers to the default route used for connections), you may have run `pppd` without the 'defaultroute' option. At this point you can try using Telnet, ftp, or finger, bearing in mind that you'll have to use numeric IP addresses unless you've set up `/etc/resolv.conf` correctly.

Setting up a Machine for Incoming PPP Connections

This first example applies to using a modem, and requiring authorization with a username and password.

```
pppd/dev/ttyM0 115200 crtscts modem 192.168.16.1:192.168.16.2 login auth
```

You should also add the following line to the file `/etc/ppp/pap-secrets`:

```
* * "" *
```

The first star (*) lets everyone login. The second star (*) lets every host connect. The pair of double quotation marks ("") is to use the file `/etc/passwd` to check the password. The last star (*) is to let any IP connect.

The following example does not check the username and password:

```
pppd/dev/ttyM0 115200 crtscts modem 192.168.16.1:192.168.16.2
```

PPPoE

1. Connect the W311/321/341's LAN port to an ADSL modem with a cross-over cable, HUB, or switch.
2. Log in to the W311/321/341 as the root user.
3. Edit the file `/etc/ppp/chap-secrets` and add the following:
`"username@hinet.net"*"password"*`

```
# Secrets for authentication using CHAP
# client      server  secret          IP addresses
"username@hinet.net" *    "password"      *
~
~
~
~
~
"chap-secrets" line 1 of 3 --33%--
```

`"username@hinet.net"` is the username obtained from the ISP to log in to the ISP account.
`"password"` is the corresponding password for the account.

4. Edit the file `/etc/ppp/pap-secrets` and add the following:
`"username@hinet.net"*"password"*`

```
# password if you don't use the login option of pppd! The mgetty Debian
# package already provides this option; make sure you don't change that.

# INBOUND connections
# Every regular user can use PPP and has to use passwords from /etc/passwd
hostname ""
"username@hinet.net" *    "password"      *
~
~
# UserIDs that cannot use PPP at all. Check your /etc/passwd and add any
# other accounts that should not be able to use pppd!
guest  hostname  "*"      -
master hostname  "*"      -
root   hostname  "*"      -
support hostname  "*"      -
stats  hostname  "*"      -

# OUTBOUND connections

# Here you should add your userid password to connect to your providers via
# PAP. The * means that the password is to be used for ANY host you connect
# to. Thus you do not have to worry about the foreign machine name. Just
# replace password with your password.
"pap-secrets" line 1 of 42 --2%--
```

`"username@hinet.net"` is the username obtained from the ISP to log in to the ISP account.
`"password"` is the corresponding password for the account.

5. Edit the file `/etc/ppp/options` and add the following line:
plugin pppoe

[illegible]

6. Add one of two files: `/etc/ppp/options.eth0` or `/etc/ppp/options.eth1`. The choice depends on which LAN is connected to the ADSL modem. If you use LAN1 to connect to the ADSL modem, then add `/etc/ppp/options.eth0`. If you use LAN2 to connect to the ADSL modem, then add `/etc/ppp/options.eth1`. The file context is shown below:

[illegible]

Type your username (the one you set in the `/etc/ppp/pap-secrets` and `/etc/ppp/chap-secrets` files) after the “name” option. You may add other options as desired.

7. Set up DNS

If you are using DNS servers supplied by your ISP, edit the file `/etc/resolv.conf` by adding the following lines of code:

```
nameserver ip_addr_of_first_dns_server
nameserver ip_addr_of_second_dns_server
```

For example:

```
nameserver 168.95.1.1
nameserver 139.175.10.20
```

8. Use the following command to create a pppoe connection:

```
pppd eth0
```

The eth0 is what is connected to the ADSL modem LAN port. The example above uses LAN1. To use LAN2, type:

```
pppd eth1
```

9. Type `ifconfig ppp0` to check if the connection is OK or has failed. If the connection is OK, you will see information about the ppp0 setting for the IP address. Use ping to test the IP.

10. If you want to disconnect it, use the kill command to kill the pppd process.

NFS (Network File System)

The Network File System (NFS) is used to mount a disk partition on a remote machine, as if it were on a local hard drive, allowing fast, seamless sharing of files across a network. NFS allows users to develop applications for the W311/321/341, without worrying about the amount of disk space that will be available. The W311/321/341 supports NFS protocol for client.

<p>NOTE Click on the following links for more information about NFS:</p> <p>http://www.tldp.org/HOWTO/NFS-HOWTO/index.html</p> <p>http://nfs.sourceforge.net/nfs-howto/client.html</p> <p>http://nfs.sourceforge.net/nfs-howto/server.html</p>

Setting up the W311/321/341 as an NFS Client

The following procedure is used to mount a remote NFS Server.

1. To know the NFS Server's shared directory.
2. Establish a mount point on the NFS Client site.
3. Mount the remote directory to a local directory.

```
#mkdir -p /home/nfs/public
```

```
#mount -t nfs NFS_Server(IP):/directory /mount/point
```

Example:

```
#mount -t nfs 192.168.3.100:/home/public /home/nfs/public
```

Mail

smtpclient is a minimal SMTP client that takes an email message body and passes it on to an SMTP server. It is suitable for applications that use email to send alert messages or important logs to a specific user.

NOTE Click on the following link for more information about smtpclient:
<http://www.engelschall.com/sw/smtpclient/>

To send an email message, use the 'smtpclient' utility, which uses SMTP protocol. Type `#smtpclient -help` to see the help message.

Example:

```
smtpclient -s test -f sender@company.com -S IP_address receiver@company.com
< mail-body-message
```

- s: The mail subject.
- f: Sender's mail address
- S: SMTP server IP address

The last mail address **receiver@company.com** is the receiver's e-mail address. **mail-body-message** is the mail content. The last line of the body of the message should contain ONLY the period '.' character.

You will need to add your hostname to the file `/etc/hosts`.

SNMP

The W311/321/341 have built-in SNMP V1 (Simple Network Management Protocol) agent software. It supports RFC1317 RS-232 like group and RFC 1213 MIB-II.

The following simple example allows you to use an SNMP browser on the host site to query the W311/321/341, which is the SNMP agent. The W311/321/341 will respond.

```

<http://www.faqs.org/rfcs/rfc1317.html>

→ W311/321/341 do NOT support SNMP trap.

OpenVPN

OpenVPN provides two types of tunnels for users to implement VPNS: **Routed IP Tunnels** and **Bridged Ethernet Tunnels**. To begin with, check to make sure that the system has a virtual device `/dev/net/tun`. If not, issue the following command:

```
# mknod /dev/net/tun c 10 200
```

An Ethernet bridge is used to connect different Ethernet networks together. The Ethernets are bundled into one bigger, “logical” Ethernet. Each Ethernet corresponds to one physical interface (or port) that is connected to the bridge.

On each OpenVPN machine, you should generate a working directory, such as `/etc/openvpn`, where script files and key files reside. Once established, all operations will be performed in that directory.

Setup 1: Ethernet Bridging for Private Networks on Different Subnets

1. Set up four machines, as shown in the following diagram.

Host A (B) represents one of the machines that belongs to OpenVPN A (B). The two remote subnets are configured for a different range of IP addresses. When this setup is moved to a public network, the external interfaces of the OpenVPN machines should be configured for static IPs, or connect to another device (such as a firewall or DSL box) first.

```
# openvpn --genkey --secret secrouter.key
```

Copy the file that is generated to the OpenVPN machine.

2. Generate a script file named **openvpn-bridge** on each OpenVPN machine. This script reconfigures interface “eth1” as IP-less, creates logical bridge(s) and TAP interfaces, loads modules, enables IP forwarding, etc.

```
#-----Start-----
#!/bin/sh

iface=eth1 # defines the internal interface
maxtap=`expr 1` # defines the number of tap devices. I.e., # of tunnels

IPADDR=
NETMASK=
BROADCAST=

# it is not a great idea but this system doesn't support
# /etc/sysconfig/network-scripts/ifcfg-eth1
ifcfg_vpn()
{
while read f1 f2 f3 f4 r3
do
if [ "$f1" = "iface" -a "$f2" = "$iface" -a "$f3" = "inet" -a "$f4" = "static" ];then
i=`expr 0`
while :
do
if [ $i -gt 5 ]; then
break
fi
i=`expr $i + 1`
read f1 f2
case "$f1" in
address ) IPADDR=$f2
```

```

        ;;
        netmask ) NETMASK=$f2
        ;;
        broadcast ) BROADCAST=$f2
        ;;
    esac
done
break
fi
done < /etc/network/interfaces
}

# get the ip address of the specified interface
mname=
module_up()
{
    oIFS=$IFS
    IFS='
'
    FOUND="no"
    for LINE in `lsmod`
    do
        TOK=`echo $LINE | cut -d' ' -f1`
        if [ "$TOK" = "$mname" ]; then
            FOUND="yes";
            break;
        fi
    done
    IFS=$oIFS

    if [ "$FOUND" = "no" ]; then
        modprobe $mname
    fi
}

start()
{
    ifcfg_vpn
    if [ ! \( -d "/dev/net" \) ]; then
        mkdir /dev/net
    fi

    if [ ! \( -r "/dev/net/tun" \) ]; then
        # create a device file if there is none
        mknod /dev/net/tun c 10 200
    fi

    # load modules "tun" and "bridge"
    mname=tun
    module_up
    mname=bridge
    module_up
    # create an ethernet bridge to connect tap devices, internal interface
    brctl addbr br0
    brctl addif br0 $iface
    # the bridge receives data from any port and forwards it to other ports.

    i=`expr 0`
    while :
    do
        # generate a tap0 interface on tun
        openvpn --mktun --dev tap${i}

        # connect tap device to the bridge
        brctl addif br0 tap${i}

        # null ip address of tap device
        ifconfig tap${i} 0.0.0.0 promisc up
    done
}

```

```

i=`expr $i + 1`
if [ $i -ge $maxtap ]; then
    break
fi
done

# null ip address of internal interface
ifconfig $iface 0.0.0.0 promisc up

# enable bridge ip
ifconfig br0 $IPADDR netmask $NETMASK broadcast $BROADCAST

ipf=/proc/sys/net/ipv4/ip_forward
# enable IP forwarding
echo 1 > $ipf
echo "ip forwarding enabled to"
cat $ipf
}

stop() {
echo "shutdown openvpn bridge."
ifcfg_vpn
i=`expr 0`
while :
do
    # disconnect tap device from the bridge
    brctl delif br0 tap${i}
    openvpn --rmtun --dev tap${i}

    i=`expr $i + 1`
    if [ $i -ge $maxtap ]; then
        break
    fi
done
brctl delif br0 $iface
brctl delbr br0
ifconfig br0 down
ifconfig $iface $IPADDR netmask $NETMASK broadcast $BROADCAST
killall -TERM openvpn
}

case "$1" in
    start)
        start
        ;;
    stop)
        stop
        ;;
    restart)
        stop
        start
        ;;
    *)
        echo "Usage: $0 [start|stop|restart]"
        exit 1
esac
exit 0
#----- end -----

```

Create link symbols to enable this script at boot time:

```

# ln -s /etc/openvpn/openvpn-bridge /etc/rc.d/rc3.d/S32vpn-br # for example
# ln -s /etc/openvpn/openvpn-bridge /etc/rc.d/rc6.d/K32vpn-br # for example

```

3. Create a configuration file named **A-tap0-br.conf** and an executable script file named **A-tap0-br.sh** on OpenVPN A.

```
# point to the peer
remote 192.168.8.174
dev tap0
secret /etc/openvpn/secrouter.key
cipher DES-EDE3-CBC
auth MD5
tun-mtu 1500
tun-mtu-extra 64
ping 40
up /etc/openvpn/A-tap0-br.sh

#-----Start-----
#!/bin/sh
# value after "-net" is the subnet behind the remote peer
route add -net 192.168.4.0 netmask 255.255.255.0 dev br0
#----- end -----
```

Create a configuration file named **B-tap0-br.conf** and an executable script file named **B-tap0-br.sh** on OpenVPN B.

```
# point to the peer
remote 192.168.8.173
dev tap0
secret /etc/openvpn/secrouter.key
cipher DES-EDE3-CBC
auth MD5 tun-mtu 1500
tun-mtu-extra 64
ping 40
up /etc/openvpn/B-tap0-br.sh

#-----Start-----
#!/bin/sh
# value after "-net" is the subnet behind the remote peer
route add -net 192.168.2.0 netmask 255.255.255.0 dev br0
#----- end -----
```

NOTE: Select cipher and authentication algorithms by specifying “cipher” and “auth”. To see with algorithms are available, type:

```
# openvpn --show-ciphers
# openvpn --show-auths
```

4. Start both of OpenVPN peers,

```
# openvpn --config A-tap0-br.conf&
# openvpn --config B-tap0-br.conf&
```

If you see the line “Peer Connection Initiated with 192.168.8.173:5000” on each machine, the connection between OpenVPN machines has been established successfully on UDP port 5000.

5. On each OpenVPN machine, check the routing table by typing the command:

```
# route
```

Destination	Gateway	Genmsk	Flags	Metric	Ref	Use	Iface
192.168.4.0	*	255.255.255.0	U	0	0	0	br0
192.168.2.0	*	255.255.255.0	U	0	0	0	br0
192.168.8.0	*	255.255.255.0	U	0	0	0	eth0

Interface **eth1** is connected to the bridging interface **br0**, to which device **tap0** also connects, whereas the virtual device **tun** sits on top of **tap0**. This ensures that all traffic from internal networks connected to interface **eth1** that come to this bridge write to the TAP/TUN device that the OpenVPN program monitors. Once the OpenVPN program detects traffic on the virtual device, it sends the traffic to its peer.

6. To create an indirect connection to Host B from Host A, you need to add the following routing item:

```
route add -net 192.168.4.0 netmask 255.255.255.0 dev eth0
```

To create an indirect connection to Host A from Host B, you need to add the following routing item:

```
route add -net 192.168.2.0 netmask 255.255.255.0 dev eth0
```

Now ping Host B from Host A by typing:

```
ping 192.168.4.174
```

A successful ping indicates that you have created a VPN system that only allows authorized users from one internal network to access users at the remote site. For this system, all data is transmitted by UDP packets on port 5000 between OpenVPN peers.

7. To shut down OpenVPN programs, type the command:

```
# killall -TERM openvpn
```

Setup 2: Ethernet Bridging for Private Networks on the Same Subnet

1. Set up four machines as shown in the following diagram:

2. The configuration procedure is almost the same as for the previous example. The only difference is that you will need to comment out the parameter "up" in "/etc/openvpn/A-tap0-br.conf" and "/etc/openvpn/B-tap0-br.conf".

Setup 3: Routed IP

1. Set up four machines as shown in the following diagram:

2. Create a configuration file named "A-tun.conf" and an executable script file named "A-tun.sh".

```
# point to the peer
remote 192.168.8.174
dev tun
secret /etc/openvpn/secrouter.key
cipher DES-EDE3-CBC
auth MD5
tun-mtu 1500
tun-mtu-extra 64
ping 40
ifconfig 192.168.2.173 192.168.4.174
up /etc/openvpn/A-tun.sh
```

```
-----Start-----
#!/bin/sh
# value after "-net" is the subnet behind the remote peer
route add -net 192.168.4.0 netmask 255.255.255.0 gw $5
-----end-----
```

Create a configuration file named B-tun.conf and an executable script file named B-tun.sh on OpenVPN B:

```
remote 192.168.8.173
dev tun
secret /etc/openvpn/secrouter.key
cipher DES-EDE3-CBC
auth MD5
tun-mtu 1500
tun-mtu-extra 64
ping 40
ifconfig 192.168.4.174 192.168.2.173
up /etc/openvpn/B-tun.sh
```

```
#-----Start-----
#!/bin/sh
# value after "-net" is the subnet behind the remote peer
route add -net 192.168.2.0 netmask 255.255.255.0 gw $5
#----- end -----
```

Note that the parameter “ifconfig” defines the first argument as the local internal interface and the second argument as the internal interface at the remote peer.

Note that **\$5** is the argument that the OpenVPN program passes to the script file. Its value is the second argument of **ifconfig** in the configuration file.

3. Check the routing table after you run the OpenVPN programs, by typing the command:

```
# route
```

Destination	Gateway	Genmask	Flags	Metric	Ref	Use	Iface
192.168.4.174	*	255.255.255.255	UH	0	0	0	tun0
192.168.4.0	192.168.4.174	255.255.255.0	UG	0	0	0	tun0
192.168.2.0	*	255.255.255.0	U	0	0	0	eth1
192.168.8.0	*	255.255.255.0	U	0	0	0	eth0

Tool Chains for Application Development

This chapter describes how to install a tool chain in the host computer that you use to develop your applications. In addition, the process of performing cross-platform development and debugging are also introduced. For clarity, the W311/321/341 embedded computer is called a target computer.

The following functions are covered in this chapter:

- ❑ **Linux Tool Chain**

- Steps for Installing the Linux Tool Chain
- Compilation for Applications
- On-Line Debugging with GDB

Linux Tool Chain

The Linux tool chain contains a suite of cross compilers and other tools, as well as the libraries and header files that are necessary to compile your applications. These tool chain components must be installed in your host computer (PC) running Linux. We have confirmed that the following Linux distributions can be used to install the tool chain.

Fedora core 1 & 2.

Steps for Installing the Linux Tool Chain

The tool chain needs about 485 MB of hard disk space. To install it, follow the steps.

1. Insert the package CD into your PC and then issue the following commands:

```
#mount /dev/cdrom /mnt/cdrom
#sh /mnt/cdrom/tool-chain/linux/install.sh
```
2. Wait for the installation process to complete. This should take a few minutes.
3. Add the directory **/usr/local/arm-linux/bin** to your path. You can do this for the current login by issuing the following commands:

```
#export PATH="/usr/local/arm-linux/bin:$PATH"
```

Alternatively, you can add the same commands to **\$HOME/.bash_profile** to make it effective for all login sessions.

Compilation for Applications

To compile a simple C application, use the cross compiler instead of the regular compiler:

```
#arm-linux-gcc -o example -Wall -g -O2 example.c
#arm-linux-strip -s example
#arm-linux-gcc -ggdb -o example-debug example.c
```

Most of the cross compiler tools are the same as their native compiler counterparts, but with an additional prefix that specifies the target system. In the case of x86 environments, the prefix is **i386-linux-** and in the case of W311/321/341 ARM boards, it is **arm-linux-**.

For example, the native C compiler is **gcc** and the cross C compiler for ARM in the W311/321/341 is **arm-linux-gcc**.

The following cross compiler tools are provided:

ar	Manages archives (static libraries)
as	Assembler
c++, g++	C++ compiler
cpp	C preprocessor
gcc	C compiler
gdb	Debugger
ld	Linker
nm	Lists symbols from object files
objcopy	Copies and translates object files
objdump	Displays information about object files
ranlib	Generates indexes to archives (static libraries)
readelf	Displays information about ELF files
size	Lists object file section sizes
strings	Prints strings of printable characters from files (usually object files)
strip	Removes symbols and sections from object files (usually debugging information)

On-Line Debugging with GDB

The tool chain also provides an on-line debugging mechanism to help you develop your program. Before performing a debugging session, add the option **-ggdb** to compile the program. A debugging session runs on a client-server architecture on which the server `gdbserver` is installed in the target computer and the client `ddd` is installed in the host computer. We'll assume that you have uploaded a program named `hello-debug` to the target computer and start to debug the program.

1. Log on to the target computer and run the debugging server program.

```
#gdbserver 192.168.4.142:2000 hello-debug
Process hello-debug created; pid=38
```

The debugging server listens for connections at network port 2000 from the network interface 192.168.4.142. The name of the program to be debugged follows these parameters. For a program requiring arguments, add the arguments behind the program name.

2. In the host computer, change the directory to where the program source resides.

```
cd /my_work_directory/myfilesystem/testprograms
```

3. Execute the client program.

```
#ddd --debugger arm-linux-gdb hello-debug &
```

4. Enter the following command at the GDB, DDD command prompt.

```
Target remote 192.168.4.99:2000
```

The command produces a line of output on the target console, similar to the following.

```
Remote debugging using 192.168.4.99:2000
```

192.168.4.99 is the machine's IP address, and 2000 is the port number. You can now begin debugging in the host environment using the interface provided by DDD.

5. Set a break point on `main` by double clicking, or by entering `b main` on the command line.
6. Click the **cont** button.

6

Programmer's Guide

This chapter includes important information for programmers.

The following functions are covered in this chapter:

- ☐ **Flash Memory Map**
- ☐ **Device API**
- ☐ **RTC (Real Time Clock)**
- ☐ **Buzzer**
- ☐ **WDT (Watch Dog Timer)**
- ☐ **UART**
- ☐ **DO**

Flash Memory Map

Partition sizes are hard coded into the kernel binary. To change the partition sizes, you will need to rebuild the kernel. The flash memory map is shown in the following table.

Address	Size	Contents
0x00000000 – 0x0003FFFF	256 KB	Boot Loader—Read ONLY
0x00040000 – 0x001FFFFFFF	1.8 MB	Kernel object code—Read ONLY
0x00200000 – 0x009FFFFFFF	8 MB	Root file system (JFFS2)—Read ONLY
0x00A00000 – 0x00FFFFFFF	6 MB	User directory (JFFS2)—Read/Write

Mount the user file system to **/mnt/usrdisk** with the root file system. Check to see if the user file system was mounted correctly. If user file system is okay, the kernel will change the root file system to **/mnt/usrdisk**. If the user file system is not okay, the kernel will use the default Moxa file system. To finish boot process, run the init program.

NOTE

1. The default Moxa file system only enables the network and CF. It lets users recover the user file system when it fails.
2. The user file system is a complete file system. Users can create and delete directories and files (including source code and executable files) as needed.
3. Users can create the user file system on the PC host or target platform, and then copy it to the W311/321/341.
4. To improve system performance, we strongly recommend that you install your application programs on the on-board flash. However, since the on-board flash has a fixed amount of free memory space, you must not over-write it, and instead use an external storage card, such as an SD or CF card, for the data log.

Device API

The W311/321/341 support control devices with the **ioctl** system API. You will need to **include** **<moxadevice.h>**, and use the following **ioctl** function.

```
int ioctl(int d, int request,...);
    Input: int d - open device node return file handle
           int request - argument in or out
```

Use the desktop Linux's man page for detailed documentation:

```
#man ioctl
```

RTC (Real Time Clock)

The device node is located at **/dev/rtc**. The W311/321/341 support Linux standard simple RTC control. You must include **<linux/rtc.h>**.

1. Function: **RTC_RD_TIME**

```
int ioctl(fd, RTC_RD_TIME, struct rtc_time *time);
```

Description: read time information from RTC. It will return the value on argument 3.

2. Function: **RTC_SET_TIME**

```
int ioctl(fd, RTC_SET_TIME, struct rtc_time *time);
```

Description: set RTC time. Argument 3 will be passed to RTC.

Buzzer

The device node is located at **/dev/console**. The W311/321/341 support Linux standard buzzer control, with the W311/321/341's buzzer running at a fixed frequency of 100 Hz. You must **include <sys/kd.h>**.

Function: KDMKTONE

```
ioctl(fd, KDMKTONE, unsigned int arg);
```

Description: The buzzer's behavior is determined by the argument arg. The "high word" part of arg gives the length of time the buzzer will sound, and the "low word" part gives the frequency.

The buzzer's on / off behavior is controlled by software. If you call the "ioctl" function, you **MUST** set the frequency at 100 Hz. If you use a different frequency, the system could crash.

WDT (Watch Dog Timer)

1. Introduction

The WDT works like a watch dog function. You can enable it or disable it. When the user enables WDT but the application does not acknowledge it, the system will reboot. You can set the ack time from a minimum of 50 msec to a maximum of 60 seconds.

2. How the WDT works

The sWatchDog is disabled when the system boots up. The user application can also enable ack. When the user does not ack, it will let the system reboot.

Kernel boot

```
.....
....
```

User application running and enable user ack

```
....
....
```

3. The user API

The user application must include **<moxadevic.h>**, and **link moxalib.a**. A makefile example is shown below:

```
all:
    arm-linux-gcc -o xxxx xxxx.c -lmoxalib
```

```
int swtd_open(void)
```

Description

Open the file handle to control the sWatchDog. If you want to do something you must first to this. And keep the file handle to do other.

Input

None

Output

The return value is file handle. If has some error, it will return < 0 value.

You can get error from `errno()`.

```
int swtd_enable(int fd, unsigned long time)
```

Description

Enable application sWatchDog. And you must do ack after this process.

Input

int fd - the file handle, from the swtd_open() return value.

unsigned long time - The time you wish to ack sWatchDog periodically. You must ack the sWatchDog before timeout. If you do not ack, the system will be reboot automatically. The minimal time is 50 msec, the maximum time is 60 seconds. The time unit is msec.

Output

OK will be zero. The other has some error, to get the error code from errno().

```
int swtd_disable(int fd)
```

Description

Disable the application to ack sWatchDog. And the kernel will be auto ack it. User does not to do it at periodic.

Input

int fd - the file handle from swtd_open() return value.

Output

OK will be zero. The other has some error, to get error code from errno.

```
int swtd_get(int fd, int *mode, unsigned long *time)
```

Description

Get current setting values.

mode –

1 for user application enable sWatchDog; need to do ack.

0 for user application disable sWatchdog: does not need to do ack.

time – The time period to ack sWatchDog.

Input

int fd - the file handle from swtd_open() return value.

int *mode - the function will be return the status enable or disable user application need to do ack.

unsigned long *time - the function will return the current time period.

Output

OK will be zero.

The other has some error, to get error code from errno().

```
int swtd_ack(int fd)
```

Description

Acknowledge sWatchDog. When the user application enable sWatchDog. It need to call this function periodically with user predefined time in the application program.

Input

int fd - the file handle from swtd_open() return value.

Output

OK will be zero.

The other has some error, to get error code from errno().

```
int swtd_close(int fd)
```

Description

Close the file handle.

Input

int fd - the file handle from swtd_open() return value.

Output

OK will be zero.

The other has some error, to get error code from errno().

4. Special Note

When you “kill the application with -9” or “kill without option” or “Ctrl+c” the kernel will change to auto ack the sWatchDog.

When your application enables the sWatchDog and does not ack, your application may have a logical error, or your application has made a core dump. The kernel will not change to auto ack. This can cause a serious problem, causing your system to reboot again and again.

5. User application example**Example 1:**

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <moxadevice.h>

int main(int argc, char *argv[])
{
    int fd;

    fd = swtd_open();
    if ( fd < 0 ) {
        printf("Open sWatchDog device fail !\n");
        exit(1);
    }
    swtd_enable(fd, 5000); // enable it and set it 5 seconds
    while ( 1 ) {
        // do user application want to do
        ....
        ....
        swtd_ack(fd);
        ....
        ....
    }
    swtd_close(fd);
    exit(0);
}
```

The makefile is shown below:

```
all:
    arm-linux-gcc -o xxxx xxxx.c -lmoxalib
```

Example 2:

```
#include <stdio.h>
#include <stdlib.h>
#include <signal.h>
#include <string.h>
#include <sys/stat.h>
#include <sys/ioctl.h>
#include <sys/select.h>
#include <sys/time.h>
#include <moxadevice.h>

static void mydelay(unsigned long msec)
{
    struct timeval time;

    time.tv_sec = msec / 1000;
    time.tv_usec = (msec % 1000) * 1000;
    select(1, NULL, NULL, NULL, &time);
}

static int swtdfd;
static int stopflag=0;

static void stop_swatcdog()
{
    stopflag = 1;
}

static void do_swatcdog(void)
{
    swtd_enable(swtdfd, 500);
    while ( stopflag == 0 ) {
        mydelay(250);
        swtd_ack(swtdfd);
    }
    swtd_disable(swtdfd);
}

int main(int argc, char *argv[])
{
    pid_t sonpid;

    signal(SIGUSR1, stop_swatcdog);
    swtdfd = swtd_open();
    if ( swtdfd < 0 ) {
        printf("Open sWatchDog device fail !\n");
        exit(1);
    }
    if ( (sonpid=fork()) == 0 )
        do_swatcdog();
    // do user application main function
    ....
    ....
    ....
    // end user application
    kill(sonpid, SIGUSR1);
    swtd_close(swtdfd);
    exit(1);
}
```

The makefile is shown below:

```
all:
    arm-linux-gcc -o xxxx xxxx.c -lmoxalib
```

UART

The normal tty device node is located at `/dev/ttyM0 ... ttyM3`.

The W311/321/341 support Linux standard termios control. The Moxa UART Device API allows you to configure ttyM0 to ttyM3 as RS-232, RS-422, 4-wire RS-485, or 2-wire RS-485. The W311/321/341 support RS-232, RS-422, 2-wire RS-485, and 4-wire RS485.

You must **include** `<moxadevice.h>`.

```
#define RS232_MODE      0
#define RS485_2WIRE_MODE 1
#define RS422_MODE      2
#define RS485_4WIRE_MODE 3
```

1. Function: `MOXA_SET_OP_MODE`

```
int ioctl(fd, MOXA_SET_OP_MODE, &mode)
```

Description

Set the interface mode. Argument 3 mode will pass to the UART device driver and change it.

2. Function: `MOXA_GET_OP_MODE`

```
int ioctl(fd, MOXA_GET_OP_MODE, &mode)
```

Description

Get the interface mode. Argument 3 mode will return the interface mode.

There are two Moxa private ioctl commands for setting up special baudrates.

Function: `MOXA_SET_SPECIAL_BAUD_RATE`

Function: `MOXA_GET_SPECIAL_BAUD_RATE`

If you use this ioctl to set a special baudrate, the termios cflag will be B4000000, in which case the B4000000 define will be different. If the baudrate you get from termios (or from calling `tcgetattr()`) is B4000000, you must call ioctl with `MOXA_GET_SPECIAL_BAUD_RATE` to get the actual baudrate.

Example to set the baudrate

```
#include <moxadevice.h>
#include <termios.h>
struct termios term;
int fd, speed;
fd = open("/dev/ttyM0", O_RDWR);
tcgetattr(fd, &term);
term.c_cflag &= ~(CBAUD | CBAUDEX);
term.c_cflag |= B4000000;
tcsetattr(fd, TCSANOW, &term);
speed = 500000;
ioctl(fd, MOXA_SET_SPECIAL_BAUD_RATE, &speed);
```

Example to get the baudrate

```
#include <moxadevice.h>
#include <termios.h>
struct termios term;
int fd, speed;
fd = open("/dev/ttyM0", O_RDWR);
tcgetattr(fd, &term);
if ( (term.c_cflag & (CBAUD|CBAUDEX)) != B4000000 ) {
    // follow the standard termios baud rate define
} else {
    ioctl(fd, MOXA_GET_SPECIAL_BAUD_RATE, &speed);
}
```

Baudrate inaccuracy

Divisor = 921600/Target Baud Rate. (Only Integer part)

ENUM = 8 * (921600/Target - Divisor) (Round up or down)

Inaccuracy = (Target Baud Rate – 921600/(Divisor + (ENUM/8))) * 100%

E.g.,

To calculate 500000 bps

Divisor = 1, ENUM = 7,

Inaccuracy = 1.7%

*The Inaccuracy should less than 2% for work reliably.

Special Note

1. If the target baudrate is not a special baudrate (e.g. 50, 75, 110, 134, 150, 200, 300, 600, 1200, 1800, 2400, 4800, 9600, 19200, 38400, 57600, 115200, 230400, 460800, 921600), the termios cflag will be set to the same flag.
2. If you use stty to get the serial information, you will get speed equal to 0.

DO

Using Dout pin 22 to control Dout close nad open , if make Pin 22 pull high being closed and Pin22 pull low being open.

Usage like:

echo "22 1 1" > /proc/driver/dio → The Do will be open

echo "22 1 0" > /proc/driver/dio → The Do will be close

Software Lock

“Software Lock” is an innovative technology developed by the Moxa engineering team. It can be adopted by a system integrator or developer to protect his applications from being copied. An application is compiled into a binary format bound to the embedded computer and the operating system (OS) that the application runs on. As long as one obtains it from the computer, he/she can install it into the same hardware and the same operating system. The add-on value created by the developer is thus lost.

Moxa’s engineering used data encryption to develop this protection mechanism for your applications. The binary file associated with each of your applications needs to undergo an additional encryption process after you have developed it. The process requires you to install an encryption key in the target computer.

1. Choose an encryption key (e.g., “ABigKey”) and install it in the target computer by a pre-utility program, ‘setkey’.

#setkey ABigKey

NOTE: set an empty string to clear the encryption key in the target computer by:

#setkey “”

2. Develop and compile your program in the development PC.
3. In the development PC, run the utility program ‘binencryptor’ to encrypt your program with an encryption key.

#binencryptor yourProgram ABigKey

4. Upload the encrypted program file to the target computer by FTP or NFS and test the program.

The encryption key is a computer-wise key. That is to say, a computer has only one key installed. Running the program ‘setkey’ multiple times overrides the existing key.

To prove the effectiveness of this software protection mechanism, prepare a target computer that has not been installed an encryption key or install a key different from that used to encrypt your program. In any case, the encrypted program fails immediately.

This mechanism also allows the computer with an encryption key to bypass programs that are not encrypted. Therefore, in the development phase, you can develop your programs and test them in the target computer cleanly.

System Commands

busybox (V0.60.4): Linux normal command utility collection

File manager

- | | |
|-----------|---|
| 1. cp | copy file |
| 2. ls | list file |
| 3. ln | make symbolic link file |
| 4. mount | mount and check file system |
| 5. rm | delete file |
| 6. chmod | change file owner & group & user |
| 7. chown | change file owner |
| 8. chgrp | change file group |
| 9. sync | sync file system, let system file buffer be saved to hardware |
| 10. mv | move file |
| 11. pwd | display now file directly |
| 12. df | list now file system space |
| 13. mkdir | make new directory |
| 14. rmdir | delete directory |

Editor

- | | |
|----------|---------------------------|
| 1. vi | text editor |
| 2. cat | dump file context |
| 3. zcat | compress or expand files |
| 4. grep | search string on file |
| 5. cut | get string on file |
| 6. find | find file where are there |
| 7. more | dump file by one page |
| 8. test | test file exist or not |
| 9. sleep | sleep (seconds) |
| 10. echo | echo string |

Network

- | | |
|--------------|------------------------|
| 1. ping | ping to test network |
| 2. route | routing table manager |
| 3. netstat | display network status |
| 4. ifconfig | set network ip address |
| 5. tracerout | trace route |
| 6. tftp | |
| 7. telnet | |
| 8. ftp | |

Process

- | | | |
|----|-------------|-----------------------------|
| 1. | kill | kill process |
| 2. | ps | display now running process |

Other

- | | | |
|-----|---------------------|---|
| 1. | dmesg | dump kernel log message |
| 2. | stty | to set serial port |
| 3. | zcat | dump .gz file context |
| 4. | mknod | make device node |
| 5. | free | display system memory usage |
| 6. | date | print or set the system date and time |
| 7. | env | run a program in a modified environment |
| 8. | clear | clear the terminal screen |
| 9. | reboot | reboot / power off/on the server |
| 10. | halt | halt the server |
| 11. | du | estimate file space usage |
| 12. | gzip, gunzip | compress or expand files |
| 13. | hostname | show system's host name |

Moxa Special Utilities

- | | | |
|----|-------------------------|--|
| 1. | backupfs | backup file system (user directory) |
| 2. | bf | built the file system (user directory) |
| 3. | kversion | show kernel version |
| 4. | cat /etc/version | show user directory version |
| 5. | upramdisk | mount ramdisk |
| 6. | downramdisk | unmount ramdisk |
